Preface

This book is designed so that it may be used in several ways: it can be used for self study, as a guide for tutorially directed work, or as a supplementary text or source of problems for an ordinary first or second course in number theory. The aim of the book is similar to that of Aufgaben und Lehrsätze aus der Analysis by Pólya and Szegö.

A considerable part of the work consists of sets of problems culminating in well known theorems. In this way much of the material of an elementary course in number theory is covered. Moreover, many theorems not often met in such elementary courses, but which require little or no greater sophistication, are included.

A large part of the book may be read by a student with little or no college mathematics. In the earlier parts of the book such a student would only infrequently find it necessary to skip a problem because of its dependence on some special mathematics not in his background.
Later in the book, especially in the last half of xiii and in xvi, xx, xxiii, xxiv the reader will need a fairly good working knowledge of limiting processes as met in elementary and advanced calculus. Some chapters, such as vi, xv, and xix, are quite technical though not advanced so far as the mathematical techniques used are concerned. Most chapters are independent of one another and even a mathematical beginner should find it relatively easy to dip and choose at random. Nevertheless, each chapter is written with the thought that most readers will wish to work it through in detail.

The solution section (pp 15-3565) is designed to serve two functions: the first is to complete the problem section in a way so as to make of the two sections together a self-contained exposition of the topics discussed; the second is to offer to the student wishing to work on his own an opportunity to (sparingly) use it for hints and ideas. This section should be well thumbed rather than well read. After saying this it should be added that many of the problems are of considerable difficulty and a reader unable to make any headway
with a problem should not feel guilty about turning to the solutions for help.

Appended to the text is a rather extended list of references, most of which have some direct bearing on at least one problem. It must, however, be emphasized that the list is not intended to be complete and contains only those references familiar to the author and felt to be particularly relevant to the material presented. Further references on virtually every topic may be found in the extraordinarily useful compendium LeVeque [1974]. Symbols such as \textsc{vii, vii 22, vii R} appearing at the end of a reference indicate, respectively, the reference is a general one for much or all of Chapter \textsc{vii}, is relevant to problem 22 of Chapter \textsc{vii}, or is mentioned in the remarks for Chapter \textsc{vii}.

Finally, a word concerning the format and style of the book is in order. It has long been the author's opinion that the format of a mathematics book is of greater importance than is generally recognized. Consequently, when the opportunity arose to have the manuscript hand calligraphed it was decided to proceed with this even though it
was necessary to begin before the entire manuscript was completed. This has led to some stylistic disadvantages in the final text. However, though their occurrence is regrettable, they do not seem to be a serious deterrent to the general aims of the presentation.

Though the author can make no claim to have written a book on a par with that by Polya and Szegö, mentioned above, that work has consistently been considered as a model for excellence. It has been an inspiration from the beginning.

Great thanks are due to Gregory Maskarinec for undertaking the arduous task of calligraphing the manuscript from a handwritten manuscript of quite different appearance. Throughout, our working relation has been excellent and left nothing to be desired. Thanks also are due to my many students who, over the years, have worked through various versions of parts of this material and to helpful colleagues for their criticisms.

All comments from readers designed to help in the improvement of the work will be gratefully received.

Joe Roberts

Portland, Oregon 1975

Other notations used in the text.

For integers:

\( a \mid b \) means there is an integer \( c \) such that \( b = a \cdot c \);

\( a \equiv b \, (\text{mod } m) \) means \( m \mid a - b \);

\( n! = 1 \cdot 2 \cdot 3 \cdot \cdots \cdot n \); \( 0! = 1 \);

\( \binom{a}{b} = \frac{a!}{(a-b)! \cdot b!}, \quad 0 \leq b \leq a \);

\( \mathbb{Z} \) is the set of positive integers;

\( \text{gcd} \) stands for "greatest common divisor";

\( [u, v] \) is the least common multiple of \( u \) and \( v \);

LHS (RHS) left (right) hand side.
ELEMENTARY NUMBER THEORY
I. The Game of Euclid — the Euclidean Algorithm

Consider the sequence of sets (duplicate elements are permitted):

{78, 35} → {43, 35} → {8, 35} → {8, 11} →
{8, 3} → {2, 3} → {2, 1} → {0, 1}.

Each set in the sequence may be obtained from the preceding one by subtracting some positive integral multiple of one of its elements from the other. When a set \{a, b\} of non-negative integers arises in this way from another such set \{m, n\} we say it is a derived set of \{m, n\}. A sequence of sets, like the above, in which each set is a derived set of the preceding set and in which the last set contains a zero will be called a derived sequence.

If \{a, b\} is a derived set of \{m, n\} with least value for \(a + b\) we call it a minimal derived set of \{m, n\}. In the above sequence \{43, 35\}
is not a minimal derived set of \( \{78,35\} \) while \( \{2,3\} \) is a minimal derived set of \( \{8,3\} \). The passage from any set to a derived set is called a move and a move to a set one element of which is 0 is called a winning move. Throughout, all integers are to be non-negative and \( m \leq n \). Further, \( \tau = \frac{1 + \sqrt{5}}{2} \).

1. Noting that \( \{m,n\} = \{n,m\} \) for all \( m,n \) we see that:

   i) \( \{m,n\} \) has \( t \) derived sets, where \( t \) is the largest positive integer for which \( tm \leq n \) is true;

   ii) \( \{m,n\} \) has exactly one minimal derived set, which is \( \{m,n-tm\} \), where \( t \) is as in (i);

   iii) if \( \{a,b\} \) is a derived set of \( \{m,n\} \) then the greatest common divisor of \( a \) and \( b \) is equal to the greatest common divisor of \( m \) and \( n \); in symbols, \( (a,b) = (m,n) \);
iv) every derived sequence starting with \( \{m, n\} \) ends with \( \{0, (m, n)\} \).

2. If two players, say A and B, start with \( \{m, n\} \) and alternately make the moves of a derived sequence, A moving first and each desiring to make the winning move of the sequence then we call the play resulting "the game of Euclid". The following assertions are true of this game:

i) if at any stage of the game a set occurs in which one element is a positive integral multiple of the other then the player next to move can win by moving to the minimal derived set;

ii) it is not always to a player's advantage to move to a minimal derived set;

iii) if there is a winning strategy for A then at each play he must select one or the other of:
the minimal derived set, or, the derived set whose
only derived set is the minimal derived set;

iv) when \(1 < \frac{a}{m} < \pi\) there is a unique move
from \([a, m]\) and that is to a set \([r, m]\) where
\[\frac{m}{r} > \pi.\]

3. i) The player moving first in the game
of Euclid, starting from \([m, n]\), \(0 < m < n\), can
force a win for himself if and only if \(\frac{n}{m} > \pi\);

ii) when a game starts with \([m, n]\) then
player A may force a win if \(\frac{n}{m} = 1\) or \(\frac{n}{m} > \pi\)
while if neither of these is true player B may
force a win.

4. An efficient method of computing the great-
est common divisor (hereafter denoted \(\gcd\)) of
two positive integers \(a\) and \(b\) is to compute a
derived sequence beginning with \([a, b]\) and in which
each other element of the sequence is the minimal
derived set of the preceding one. Thus if \( a > b \) and \( a = qb + r, 0 \leq r < b \), where \( q \) and \( r \) are integers, the first move would be \( \{a, b\} \rightarrow \{b, r\} \).

Putting \( a = r_0, b = r_1, q = q_0, r = r_2 \), etc., one finds the \( \text{gcd} \) of \( a \) and \( b \) is \( r_n \) when

\[
\begin{align*}
  r_0 &= q_0 r_1 + r_2 & 0 < r_2 < r_1 \\
  r_1 &= q_1 r_2 + r_3 & 0 < r_3 < r_2 \\
  r_2 &= q_2 r_3 + r_4 & 0 < r_4 < r_3 \\
  & \vdots \\
  r_{n-2} &= q_{n-2} r_{n-1} + r_n & 0 < r_n < r_{n-1} \\
  r_{n-1} &= q_{n-1} r_n + 0
\end{align*}
\]

This process is called the Euclidean Algorithm. In the process the \( \text{gcd} \) of the starting numbers is the last non-zero "remainder".

5. Using the Euclidean algorithm it is not hard to see that given any positive integers \( a \) and \( b \) there exist positive integers \( x \) and \( y \) for which

\[ (a, b) = ax - by. \]
We call expressions like $ax - by$ or $ax + by$
linear combinations of $a$ and $b$.

6. It is interesting to ask how efficient the
Euclidean algorithm is for the determination of
the gcd of two numbers. Information about
this question is given in a theorem due to Lamé.
To prove the theorem we will make use of the
Fibonacci sequence $u_0,u_1,u_2,...$ defined by:

$$u_0 = u_1 = 1,$$

$$u_{n+2} = u_{n+1} + u_n$$ for $n > 0$.

i) For $n \geq 1$, $u_{5n+1} \geq 10^n$, so $u_{5n+1}$ has
at least $n+1$ base 10 digits;

ii) If $n$ steps are used in the Euclidean
algorithm determining the gcd of $r_0$ and $r_1$,
$r_0 > r_1 > 0$, using $r_1$ as the first divisor, then
$r_1 \geq u_n$;
iii) (Lamé [1844]) the number of divisions needed by the Euclidean algorithm in finding the gcd of two numbers does not exceed five times the number of base 10 digits in the smaller of the two numbers;

iv) the maximum number of divisions allowed by (iii) is actually used in computing the gcd's of $(8, 13), (89, 144), (987, 1597)$ by the Euclidean algorithm; note that all numbers involved are in the Fibonacci sequence;

v) if the Euclidean algorithm in computing the gcd of $a$ and $b$, $a > b$, $b$ having $t$ base 10 digits, takes $st$ steps then the number of base 10 digits of $u_{st}$ is $\leq t$;

vi) \[ \left| \frac{u_{n+1}}{u_n} - \tau \right| < \frac{1}{u_0^2} \];

vii) \[ u_{n+s} > 10u_n \text{ for } n \geq 4 \];

viii) for $t \geq 4$, $u_{st} > 10^t$ and, therefore, $u_{st}$ has more than $t$ base 10 digits;
ix) the Euclidean algorithm when applied to two numbers the smaller of which has at least 4 base 10 digits never takes as many divisions as allowed by Lamé's theorem; i.e. Lamé's theorem is not "best possible" when applied to numbers the smaller of which is \( \geq 10^3 \).

Remarks.
The game of Euclid is due to Cole & Davie [1969] and has been further analysed by Spitznagel [1973]. The theorem of Lamé was first proved by him in 1844. The result in \( \pi_6(ix) \) is far from the best known result of this kind. The interested reader might consult Dubisch [1949], Dixon [1971], Brown [1967], or Plankensteiner [1970] for further information and references.
The point $C$ divides $A \quad C \quad \frac{r}{m} \quad B$ a line segment $AB$ into "extreme and mean ratio" (Euclid, Book IV, Definition 3) when \[ \frac{m}{r} = \frac{m+r}{m}. \]

Such a division of a line segment is sometimes called a golden section or a golden cut. The ratio $\frac{m}{r}$ for such a division is called the golden mean or the golden ratio. A rectangle whose sides are in this ratio is a golden rectangle. In the following we again use $\tau$ for the irrational number $\frac{1 + \sqrt{5}}{2}$ and use $\tau'$ for its "conjugate" $\frac{1 - \sqrt{5}}{2}$.

1. If $0 < r < m$ and \[ \frac{m}{r} = \frac{m+r}{m} \] then \[ \frac{m}{r} = \tau. \]

2. $\tau^2 = 1 + \tau$, $\tau^{-1} = \tau - 1$, and $\frac{1}{\tau} = -\tau'$. 
3. If \( r \) and \( m \) are positive numbers with \( \frac{m}{r} \neq \frac{m+r}{m} \) then \( \tau \) lies strictly between \( \frac{m}{r} \) and \( \frac{m+r}{m} \). Further, no other number shares this property with \( \tau \), even if \( r \) and \( m \) are constrained to be integers.

4. Consider the sequence

\[
\frac{m}{r}, \frac{m+r}{m}, \frac{2m+r}{m+r}, \frac{3m+2r}{2m+r}, \frac{5m+3r}{3m+2r}, \ldots
\]

where each term has a numerator which is the sum of the previous numerator and denominator and has a denominator which is the previous numerator.

i) If \( c = \min \{ r, m \} \), i.e. \( c = r \) if \( r \leq m \) and \( c = m \) if \( m < r \), then the numerator of the \( n^{th} \) term is \( \geq nc \) and, therefore, when \( r \) and \( m \) are positive both numerator and denominator increase without bound.

ii) Given 3 consecutive terms of the sequence,
say $\frac{a}{b}$, $\frac{c}{d}$, $\frac{e}{f}$, it is true that

$$ad - bc = -(cf - de);$$

iii) If $\alpha = |m^2 - mr - r^2|$ then the sequence of moduli of the successive differences in the given sequence is

$$\frac{\alpha}{m^r}, \frac{\alpha}{m(m+r)}, \frac{\alpha}{(m+r)(2m+r)}, \ldots;$$

iv) the sequence converges to $\tau$.

5. Consider the sequence of #4 in the special case $m = r = 1$:

$$\frac{1}{1}, \frac{2}{3}, \frac{3}{5}, \frac{5}{8}, \frac{8}{13}, \ldots$$

The sequence $1, 1, 2, 3, 5, 8, \ldots$ of denominators is the Fibonacci sequence and is denoted by $u_0, u_1, u_2, \ldots$ (see I #6).

i) $u_{n+2} = u_{n+1} + u_n$ for $n \geq 0$;

ii) $(u_{n+1}, u_n) = 1$ for $n \geq 0$;

iii) $u_n^2 - u_{n-1}u_{n+1} = (-1)^n$ for $n \geq 1$;

iv) $u_n \geq n$;
v) \[ \left| \frac{u_{n+1}}{u_n} - \tau \right| < \frac{1}{u_n^2} ; \]
vii) \[ \frac{u_{n+1}}{u_n} \to \tau \text{ as } n \to \infty . \]

6. i) \( \tau^{n+1} = u_{n-1} + u_n \tau \) for \( n \geq 1 \);
ii) \( (-1)^n \tau^{-(n+1)} = u_n \tau^{-1} - u_{n-1} \) for \( n \geq 1 \);
iii) (Binet 1843)
\[ u_n = \frac{1}{\sqrt{5}} \left( \tau^{n+1} - \tau^{-n+1} \right) \text{ for } n \geq 0 . \]

7. Consider the triangle inscribed in a rectangle as shown.

i) If the triangles A, B, C are equal in area then P and Q cut their respective sides in the golden ratio;

ii) If, in addition, \( a = \delta \) then the large rectangle is golden.

8. The diagonal of a regular pentagon with side 1 is \( \tau \).
9. The lengths of the segments of the dark zigzag line in the "star-pentagram" are as indicated. Further, the process may be continued indefinitely both in the inward and outward directions. The diagonal of the large pentagon is of length $\tau^2$.

10. One may cut a square into four pieces, as indicated, in such a way that the four pieces may be reassembled into a non-square rectangle.

11. (Schlegel) Attempting to carry out the decomposition of #10 with dimensions as shown at the right leads to a surprising result when one constructs a model.
12. i) \( \tau = 1 + \frac{1}{\tau} = 1 + \frac{1}{1 + \frac{1}{\tau}} = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{\tau}}} = \ldots \), and the "pieces" of the limiting "continued fraction" \( 1 + \frac{1}{1 + \frac{1}{1 + \ldots}} \) are

\( 1, 1 + \frac{1}{1} = 2, 1 + \frac{1}{1 + \frac{1}{1}} = \frac{3}{2}, 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1}}} = \frac{5}{3}, \ldots \)

with the general one being \( \frac{u_{n+1}}{u_n} \);

ii) it is entirely reasonable to write

\( \tau = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \ldots}}} \).

13. For \( m \geq 1, n \geq 1 \):

i) \( u_{m+n} = u_{m-1}u_{n-1} + u_mu_n \);

ii) \( u_{n-1} \) divides \( u_{nm-1} \);

iii) \( (u_{n-1}, u_{m-1}) = u_{(n,m)-1} \).

14. Using matrix multiplication one has

\[
\begin{pmatrix}
1 & 1 \\
1 & 0
\end{pmatrix}^n = \begin{pmatrix} u_n & u_{n-1} \\ u_{n-1} & u_{n-2} \end{pmatrix} \text{ for } n \geq 2.\]
15. Let $A_n$ be the set of all those subsets of $\{1, 2, \ldots, n\}$ containing no pair of consecutive integers. Further, let $q(n)$ be the cardinality of $A_n$ and let $f(n, k)$ be the number of elements in $A_n$ having exactly $k$ elements. Then

i) $q(n) = q(n-1) + q(n-2)$ for $n > 2$;

ii) $q(n) = u_{n+1}$ for $n \geq 1$;

iii) the number of strings of $k$ 1's and $n-k$ 0's in which no two 1's are consecutive is just $f(n, k)$;

iv) the number of ways of placing $k$ 1's into $n-k+1$ boxes so that no box has more than 1 element is exactly $f(n, k)$;

v) $f(n, k) = \binom{n-k+1}{k}$ when $2k \leq n+1$ and is 0 otherwise;

vi) setting $\binom{s}{k} = 0$ when $s < t$ we have $u_n = \sum_{k=0}^{n-1} \binom{n-k}{k}$, for $n \geq 1$. 

vii) the sums in the indicated slant rows of Pascal's triangle are consecutive terms of the Fibonacci sequence.

\[
\begin{array}{cccccccc}
1 & 1 \\
1 & 2 & 1 \\
1 & 3 & 3 & 1 \\
1 & 4 & 6 & 4 & 1 \\
1 & 5 & 10 & 10 & 5 & 1 \\
1 & 6 & 15 & 20 & 15 & 6 & 1 \\
1 & 7 & 21 & 25 & 25 & 21 & 7 & 1
\end{array}
\]

16. Let \( U \) be the power series

\[1 + x + 2x^2 + 3x^3 + 5x^4 + 8x^5 + 13x^6 + \cdots\]

Then:

i) \( U \) converges to \( \frac{1}{1-x-x^2} \) for \( |x| < \tau^{-1} \);

ii) \[ \frac{1}{1-x-x^2} = \frac{1}{r-s} \left\{ \frac{r}{1-\tau x} - \frac{s}{1-\tau' x} \right\}, \]

where \( r + s = 1 = -rs \);

iii) from (ii) one sees

\[ u_n = \frac{1}{\sqrt{5}} \left\{ \tau^{n+1} - \tau'^{n+1} \right\}; \]

(compare with \#6(ii));

w) \[ \frac{100000}{9899} = 1.0102030508132134559 \cdots; \]

v) \[ 1 + 2 + 3 + \cdots + u_n = u_{n+2} - 2. \]
Remarks.

1. The Fibonacci sequence seems to have originated in connection with the famous rabbit problem posed by Leonardo of Pisa (Fibonacci) in 1202. One phrasing of the problem is as follows.

One places a pair of rabbits in a confined area. How many pairs of rabbits can be produced in a year if every month each pair begets a new pair which from the second month itself becomes productive?

It will be noted that the sequence of numbers obtained for the numbers of pairs of rabbits at the ends of consecutive months is just the Fibonacci sequence.
2. The Pythagoreans were so taken by the properties of the star-pentagram (see e.g. p. 9) that they used it as a symbol of recognition and brotherhood. In his book Science Awakening [1954 p. 101] van der Waerden tells a charming story of this.

3. The “paradoxical” decomposition of π11 seems to go back to Schlegel [1868]. See also Coxeter [1953].

4. The frequent occurrence, in a wide variety of settings, of the golden mean and the Fibonacci numbers has lead in recent years to a new mathematics journal, The Fibonacci Quarterly. Besides this journal the interested reader
might consult any of the following for further information: Coxeter [1953], Gardner [1959], Pacioli [1509, reprint 1956], Huntley [1970], Archibald [1918], Thompson [1952].
Ⅲ Prime Factorizations & Primes

A positive integer $n$ which satisfies an equation $n = ab$, where $a$ and $b$ are integers larger than 1, is called a composite integer. If $n$ is neither composite nor equal to 1 it is called prime.

1. Every integer larger than 1 has at least one prime divisor. (This prime divisor may be the number itself.)

2. Each integer larger than 1 is either prime or a product of two or more primes; i.e. each integer larger than 1 has a prime factorization.

3. If a prime number divides a product of two integers then that prime must divide one or the other of the two integers.
4. The prime factorization of an integer larger than 1 is unique except for the order in which the factors occur.

5. Given any integer \( n \) there is a prime factor of \( 1 + n! \) exceeding \( n \). Therefore there are infinitely many primes.

6. The last conclusion of #5 also follows from observing that every prime factor of \( 1 + p_1 \cdots p_k \), where each of \( p_1, \ldots, p_k \) is prime, differs from each of \( p_1, \ldots, p_k \). (This proof was given by Euclid in his Elements.)

7. Given a positive integer \( k \geq 2 \) there exists a string of \( k \) consecutive composite integers.

8. If \( p_1, \ldots, p_k \) is any finite collection of primes the number \( 4p_1 \cdots p_k - 1 \) contains a prime factor
of the form $4k+3$ and this prime differs from each of $p_1, \ldots, p_k$. Therefore, there are infinitely many $4k+3$ primes.

9. Let $F_n = 2^{2^n} + 1$ for $n = 0, 1, 2, \ldots$. These numbers are called Fermat numbers.

i) The base 10 unit's digit of $F_n$, $n \geq 2$, is 7;

ii) if $2^m + 1$ is prime then $m$ is a power of 2; i.e. $2^m + 1$ is a Fermat number whenever it is a prime;

iii) though Fermat thought all $F_n$ to be prime this is not the case since, as Euler first observed, 641 is a prime divisor of $F_5$;

\[ \prod_{0 \leq n < m} F_n = F_m - 2; \]

6) $(F_n, F_m) = 1$ for $n \neq m$;

v) $(\bar{w}-6)$ implies the infinitude of the number of primes.
10. No integral polynomial has only prime values for all sufficiently large integers. (By "integral polynomial" we mean a polynomial with integer coefficients.)

11. (Luthar) Write \( x_n = p_1 + \cdots + p_n \), \( n \geq 1 \), where \( p_j \) is the \( j^{th} \) prime number.

i) \( p_{n+1} > 2n + 1 \) for \( n \geq 4 \);

ii) \( x_n > n^2 \) for \( n \geq 1 \);

iii) \( p_{n+1} \leq 2(n+k) + 1 \) implies

a) \( k > 0 \);

b) \( p_{n-j} \leq 2(n+k) - (2j+1) \) for \( 0 \leq j < n \);

c) \( x_n < (n+k)^2 \);

iv) \( (n+k)^2 \leq x_n < (n+k+1)^2 \) implies \( p_{n+1} > 2(n+k) + 1 \);

v) for \( n \geq 1 \) there is a square strictly between \( x_n \) and \( x_{n+1} \).
12. (Grimm) For each $k$, $2 \leq k \leq n$, put

$$ q_k = \begin{cases} k & \text{if } \frac{n}{2} < k \leq n \text{ and } k \text{ is prime;} \\ \text{any prime factor of } \frac{n!}{k} + 1 & \text{otherwise.} \end{cases} $$

i) $q_k \mid n! + k$ ;

ii) $q_k \mid n! + j$, $2 \leq j \leq n$, implies $j = k$ ;

iii) $q_2, \ldots, q_n$ are pairwise distinct ;

iv) it is possible to select $n-1$ pairwise distinct prime divisors, one from each of $n! + 2, \ldots, n! + n$.

Remarks.

1. Results such as the one proved in #8 are very special cases of a general theorem of Dirichlet to the effect that every arithmetic progression $a, a+b, a+2b, a+3b, \ldots$ for which $(a,b) = 1$ contains infinitely many primes (see XXIV).
2. The only known prime $F_n$ (see #9) are those with $n = 0, 1, 2, 3, 4$. There are 38 values of $n$ for which $F_n$ is known to be composite. These are: 5 through 16, 18, 19, 23, 36, 38, 39, 55, 58, 63, 73, 77, 81, 117, 125, 144, 150, 207, 226, 228, 260, 267, 268, 284, 316, 452, 1945. The number $F_{17}$ has more than 30,000 digits and its character is not known. Until very recently (1971) $F_7$ was known to be composite but its factorization was not known. In 1971 this number was factored by Morrison and Brillhart and it was found that $F_7 = 340,282,366,920,938,463,463,374,607,431,768,211,457 \times (59,649,589,127,497,217)(5,704,689,200,685,129,054,721)$. The number of digits in $F_{1945}$ exceeds $10^{582}$ but nevertheless it is known that $5 \cdot 2^{1947} + 1$ is its smallest prime divisor. Further information about Fermat primes may be found in [xix]. The interested reader might also consult Sierpinski [1964a,b].
3. Despite the truth of the result in #10 it has recently been proved, as a consequence of Matijasevich's solution of Hilbert's Tenth Problem, that there do exist integral polynomials whose positive range consists precisely of the prime numbers. (See Davis [1973].)

4. Problems #11, 12 are due, respectively, to Luthar [1969], and Grimm [1961, 1969]. For related work to #12 see Just [1972] and Cjjsouw, Tijdeman [1972].
IV Square Brackets

The largest integer not exceeding \( x \) is denoted by \([x]\). Thus \([\pi]\) = 3, \([\frac{1}{2}]\) = 0, \([-\pi]\) = -4, etc. This function appears in a number of diverse settings. In this chapter we set forth a number of its properties as well as use it in expressions for various other number theoretic functions. Throughout the chapter we use \( m, n, k \) for integers and \( \alpha \) and \( \beta \) for arbitrary real numbers.

1. \( \alpha - 1 < [\alpha] \leq \alpha \) and \([\alpha] \leq \alpha < [\alpha] + 1\).

2. \([\alpha + n] = [\alpha] + n\).

3. \( \frac{m+1}{n} \leq [\frac{m}{n}] + 1 \), \( n > 0 \).

4. \([\frac{[\alpha]}{n}] = [\frac{\alpha}{n}] \), \( n > 0 \).
5. No integer is closer to $\alpha$ than $[\alpha + \frac{1}{2}]$.

6. $-[-\alpha]$ is the smallest integer not less than $\alpha$.

8. $[\alpha + \beta] + [\alpha] + [\beta] \leq [2\alpha] + [2\beta]$.

9. $[\alpha][\beta] \leq [\alpha\beta] \leq [\alpha][\beta] + [\alpha] + [\beta]$, for $\alpha > 0, \beta > 0$.

10. When $0 < k \leq \alpha$, $[\frac{\alpha}{k}]$ is the number of positive integral multiples of $k$ not exceeding $\alpha$.

11. When $\alpha > \beta$, $[\alpha] - [\beta]$ is the number of integers $m$ satisfying $\beta < m \leq \alpha$.

12. $[\alpha] + [-\alpha] = \begin{cases} 0 & \text{if } \alpha \text{ is an integer;} \\ -1 & \text{otherwise.} \end{cases}$
13. \([\alpha] - 2[\frac{\alpha}{2}]\) is either 0 or 1.

14. \([\frac{n}{2}] - [-\frac{n}{2}] = n\).

15. \(\lim_{n \to \infty} \frac{[n\alpha]}{n} = \alpha\).

16. \([\sqrt[n]{\alpha}] = [\sqrt[n]{[\alpha]}]\) for \(\alpha \geq 0\).

17. \([\alpha] + [\alpha + \frac{1}{n}] + [\alpha + \frac{2}{n}] + \ldots + [\alpha + \frac{n-1}{n}] = [n\alpha]\).

18. \([\frac{\alpha}{n}] + [\frac{\alpha + 1}{n}] + \ldots + [\frac{\alpha + n-1}{n}] = [\alpha]\).

19. \([m\alpha] + [m\alpha + \frac{m}{n}] + \ldots + [m\alpha + \frac{(n-1)m}{n}] = [n\alpha] + [n\alpha + \frac{n}{m}] + \ldots + [n\alpha + \frac{(m-1)n}{m}]\).

20. When \(n\) and \(m\) are of opposite parity
\[
\int_0^1 (-1)^{[nx] + [mx]} (\frac{n-1}{[nx]})(\frac{m-1}{[mx]}) \, dx = 0.
\]
21. \[ \tau^2 n = [\tau [\tau n] + 1], \] when \( \tau = \frac{1 + \sqrt{5}}{2}. \)

22. (Skolem) \[ \sqrt{2} \left((1 + \frac{1}{\sqrt{2}}) n + \frac{1}{2}\right) = \left((1 + \sqrt{2}) n\right). \]

23. \( u_n = \left[ \sqrt{3} \left(\frac{1 + \sqrt{3}}{2}\right)^{n+1} + \frac{1}{2}\right], \) where \( u_n \) is the \( n+1 \) \text{st} Fibonacci number.

24. If \( p \) is a prime number then the highest power of \( p \) in \( n! \) is \( \left[ \frac{n}{p} \right] + \left[ \frac{n}{p^2} \right] + \left[ \frac{n}{p^3} \right] + \cdots. \)

25. Problem 24 may be used to show:
   
   i) \( \left(\frac{n}{m}\right) \) is an integer;
   
   ii) \( \frac{(n_1 + \cdots + n_k)!}{n_1! \cdots n_k!} \) is an integer;
   
   iii) (Catalan) \( \left(\frac{m+n}{m}\right) \) divides \( \left(\frac{2m}{m}\right)\left(\frac{2n}{n}\right). \)

26. \( n \) is a prime if and only if \( \sum_{m=1}^{\infty} \left(\frac{n}{m}\right) - \left[\frac{n-1}{m}\right] = 2. \)

27. (R. Algee) The number of primes not exceeding \( n \) is \( \sum_{n=2}^{m} \left[ \frac{n/\alpha}{n/\alpha} \right]. \)
28. \( \lim_{m \to \infty} [\cos^2 m! \pi x] = \begin{cases} 0 & \text{for } x \text{ irrational;} \\ 1 & \text{for } x \text{ rational.} \end{cases} \)

29. If \( N \) is the number of solutions of the system \( xy \leq n, 0 < x, 0 < y \), then
\[
N = \left[ \frac{n}{1} \right] + \left[ \frac{n}{2} \right] + \cdots + \left[ \frac{n}{\sqrt{n}} \right] = 2 \sum_{k=1}^{\left[ \sqrt{n} \right]} \left[ \frac{n}{k} \right] - \left[ \sqrt{n} \right]^2.
\]

30. For 6 odd there is an integer \( q \) such that:
   i) \( 0 \leq x - 6q < \frac{6}{2} \) if and only if \( \left[ \frac{2x}{6} \right] \) is even;
   ii) \( -\frac{6}{2} < x - 6q < 0 \) if and only if \( \left[ \frac{2x}{6} \right] \) is odd.

31. i) \( \sum_{n=1}^{6-1} \left[ \frac{an}{b} \right] = \frac{(a-1)(b-1)}{2} + \frac{d-1}{2} \), where \( d = (a, 6) \);

ii) (Eisenstein)
\[
\sum_{n=1}^{6-1} \left[ \frac{an}{b} \right] + \sum_{n=1}^{a-1} \left[ \frac{bn}{a} \right] = \frac{(a-1)(b-1)}{4},
\]
when \( a \) and \( b \) are relatively prime odd positive integers.
32. Let \((a, b) = 1\) and suppose \(ax_0 + by_0 = 1\). Further, consider the equation

\[(*) \quad ax + by = k.\]

A pair of integers \(x, y\) satisfying \((*)\) is called a solution of the equation and if, in addition, both \(x\) and \(y\) are non-negative, we call \(x, y\) a non-negative solution.

i) If \(x, y\) is a solution of \((*)\) then there is an integer \(t\) such that

\[x = kx_0 + bt,\]
\[y = ky_0 - at;\]

ii) the number of non-negative solutions of \((*)\) is given by \(N = 1 + \left[\frac{kx_0}{b}\right] + \left[\frac{ky_0}{a}\right];\)

iii) for \(k \geq 0\), \((*)\) has no non-negative solutions precisely when there exist \(r, s, 0 \leq r < b, 0 \leq s < a\) such that

\[k = ar + bs - ab;\]
\[ \text{iv) } (\times) \text{ always has a non-negative solution when } k > ab - a - b \text{ but does not have a non-negative solution when } k = ab - a - b; \]

\[ \text{v) for exactly } \frac{(a-1)(b-1)}{2} \text{ positive values of } k \text{ does } (\times) \text{ fail to have a non-negative solution.} \]

**Remarks.**

1. There is a wide literature on square brackets. The interested reader might consult the following: Bang [1957]; Beatty [1927]; Coxeter [1953]; Fraenkel [1969]; Fraenkel, Levitt, Shimshoni [1972]; Graham, Pollack [1970]; Graham [1973]; Skolem [1957]; Watson [1956].
2. The result in #32 (iv) goes back to Frobenius and Schur. Similar results have been sought for the general linear forms

\[ a_1 x_1 + \cdots + a_k x_k = n \]

but even for \( k = 3 \) the general solution is not known. For an introduction to the literature the reader might consult Brauer, Shockley [1962], Erdős, Graham [1971], Hofmeister [1966], Lewin [1972, 1973], Roberts [1956], Bateman [1958], and Note 14 by Skolem in Netto [1927].
v Kronecker Theorems

For \( x \) a real number we write \((x)\) for the fractional part of \( x \); i.e. \((x) = x - [x]\).

1. Let \( \alpha \) be irrational and put \( P_n = \left( n \alpha \right) \).
   Then:
   i) \( 0 < P_n < 1 \), \( n = 1, 2, \ldots \);
   ii) \( P_n \neq P_m \) for \( n \neq m \);
   iii) given \( \varepsilon > 0 \) there are positive integers \( n \) and \( r \) such that \( |P_n - P_{n+r}| < \varepsilon \);
   iv) given \( \varepsilon > 0 \) there is an \( r \) such that \( P_r < \varepsilon \) or \( 1 - \varepsilon < P_r \);
   v) (Kronecker's one dimensional theorem) \( \{P_1, P_2, \ldots\} \) is dense in the open unit interval.

2. Define the mapping \( f \) of the plane into the unit square by \( f(x, y) = ((x), (y)) \).
Further, suppose \( \alpha, \beta \) irrational and 
\( P_n = f(n\alpha, n\beta), n = 1, 2, \ldots \). Write \( PQ \) for 
the vector from \( P \) to \( Q \) and \( |PQ| \) for the 
length of this vector.

Then:

i) \( P_n \neq P_m \) for \( n \neq m \);

ii) if \( P_m Q = P_n P_{n+r} \) then \( f(Q) = P_{m+r} \);

iii) if \( P_1 Q = mP_1 P_{1+r} + nP_1 P_{1+s} \) then

\[ f(Q) = P_{1+mr+ns} \];

iv) if \( P_1 P_{1+r} \) and \( P_1 P_{1+s} \) are not parallel
and \( L \) is the greatest of their lengths then
every point of the unit square is within \( L \) of
some point of the form \( P_{1+mr+ns} \), where \( m \)
and \( n \) are non-negative integers.

3. Let \( P_1, P_2, \ldots \) be as in \#2 and suppose
that the only triple of integers \( r, s, t \)
for which \( r\alpha + s\beta + t = 0 \) is \( 0, 0, 0 \);
i.e. $\alpha, \beta, \gamma$ are rationally independent.

Then:

i) $\alpha$ and $\beta$ are irrational;

ii) given $\varepsilon > 0$, there are integers $n$ and $r$ such that $|P_n P_{n+r}| < \varepsilon$;

iii) for $0 < \varepsilon < \min \{ (\alpha), 1-(\alpha), (\beta), 1-(\beta) \}$ and $n, r$ as in (ii) the vector $P_n P_{n+r}$ equals $P_n P_{n+r}$;

iv) for $\varepsilon$ as in (iii) there are infinitely many positive integers $r$ such that $|P_n P_{n+r}| < \varepsilon$;

v) it is not possible that infinitely many of the vectors $P_{n} P_{n+r}$ appearing in (i) be parallel;

vi) (Kronecker's two dimensional theorem) \{ $P_1, P_2, \ldots$ \} is dense in the unit square.

Remark.

For expositions of the theorems in this chapter see Niven [1963] and Hardy and Wright [1962].
VI Beatty, Skolem Theorems

Let $s(\alpha)$ be the sequence $[\alpha], [2\alpha], [3\alpha], \ldots$ and let $A(\alpha)$ be the set of distinct elements of $s(\alpha)$. (In the following we use $\mathbb{Z}$ for the set of positive integers and, as before, $\tau$ for $\frac{1+\sqrt{5}}{2}$.) Then (for $\alpha, \beta$ positive):

1. $A(\alpha)$ is precisely the set of non-negative integers when $0 < \alpha < 1$.

2. $A(\alpha) \cap A(\beta) = \emptyset$ implies $\alpha > 1$ and $\beta > 1$.

3. $A(\alpha) \subseteq A\left(\frac{\alpha}{m}\right)$.

4. $A\left(1 + \sqrt{2}\right) \nsubseteq A(\sqrt{2})$.

5. $A(\alpha) \cap A(\beta)$ is an infinite set when both $\alpha$ and $\beta$ are rational.
6. (Beatty) If $\alpha$ is positive and irrational and $\frac{1}{\alpha} + \frac{1}{\beta} = 1$ then every positive integer is in exactly one of $S(\alpha)$, $S(\beta)$ and these sequences have no duplicate terms.

7. $A(\sqrt{2}) \cap A(2 + \sqrt{2}) = \emptyset$ and $A(\sqrt{2}) \cup A(2 + \sqrt{2}) = \mathbb{Z}.$

8. $A(\tau) \cap A(\tau^2) = \emptyset$ and $A(\tau) \cup A(\tau^2) = \mathbb{Z}.$

9. (Skolem) The three sequences $(n \geq 1)$
\[
\{ [\tau [ \tau n ]] \}, \quad \{ [\tau [ \tau^2 n ]] \}, \quad \{ [ \tau^2 n ] \}
\]
are mutually disjoint and their union is $\mathbb{Z}.$

10. If $A_0 = A(\tau)$ and $A_{m+1} = \{ [\tau^2 n] \mid n \in A_m \}$ for $m \geq 0,$ then the $A_i$ are disjoint in pairs and their union is $\mathbb{Z}.$
11. If $\alpha$ is positive and irrational and 
$\frac{1}{\alpha} + \frac{1}{\beta} = 1$ and if $A_0 = A(\alpha)$, $A_{m+1} = \{[\beta n] | n \in A_m\}$ 
for $m \geq 0$, then the $A_j$ are disjoint in pairs 
and their union is $\mathbb{Z}$.

12. If $A(\alpha) \cap A(\beta)$ is finite and $A(\alpha) \cup A(\beta) = \mathbb{Z}$ 
then $\frac{1}{\alpha} + \frac{1}{\beta} = 1$.

13. $A(\alpha) \cap A(\beta)$ non-empty and finite is 
incompatible with $A(\alpha) \cup A(\beta) = \mathbb{Z}$.

14. (Bang) A necessary and sufficient 
condition for $S(\alpha), S(\beta)$ to be complementary 
(i.e. $A(\alpha) \cap A(\beta) = \emptyset$, $A(\alpha) \cup A(\beta) = \mathbb{Z}$) is 
that $\alpha$ and $\beta$ be positive irrational numbers 
such that $\frac{1}{\alpha} + \frac{1}{\beta} = 1$. 
15. (Uspensky) An interesting result along the lines of #6 and #9 is the following theorem proved by Uspensky in 1927.

There do not exist 3 or more numbers $\alpha_1, \ldots, \alpha_n$ such that $S(\alpha_1), \ldots, S(\alpha_n)$ are non-empty disjoint sequences which taken together contain each positive integer precisely once.

We prove this following Graham [1963]. In fact we shall assume: $n \geq 3$, $\alpha_1 < \ldots < \alpha_n$ and $S(\alpha_1), \ldots, S(\alpha_n)$ are non-empty disjoint sets exhausting the integers without duplication and shall show that this leads to a contradiction. Throughout, $m$ is the least positive integer not in $S(\alpha_1)$.

i) $\alpha_1 = 1 + \delta$ where $0 < \delta < 1$;

ii) $S(\alpha_1)$ does not miss any pair of consecutive integers;

iii) $(m-1) \delta < 1 \leq m \delta$;
iv) \( m \) is the first element of \( S(\alpha_2) \) and 
\[ \alpha_2 = m + \epsilon, \quad 0 \leq \epsilon < 1; \]
v) if \( x \) is a positive integer not in \( S(\alpha_1) \) the next positive integer not in \( S(\alpha_1) \) is 
either \( x + m \) or \( x + m + 1 \); 
vii) the next element after \( \lceil n \alpha_2 \rceil \) in \( S(\alpha_2) \) is either \( \lceil n \alpha_2 \rceil + m \) or \( \lceil n \alpha_2 \rceil + m + 1 \); 
viii) the \( k^{th} \) positive integer missing from \( S(\alpha_1) \) is the \( k^{th} \) element in \( S(\alpha_2) \); 
viiii) the assumption is false.

16. Let \( \alpha \) and \( \beta \) be positive irrational numbers and suppose \( a, b, c \) are integers such that \( \frac{a}{\alpha} + \frac{b}{\beta} = c \neq 1, \quad a > 0, \quad (a, b, c) = 1. \) Further, let \( \alpha' = (a, b) \) and denote the shaded rectangle in the diagram by \( S. \)
(ii) if $b < 0$ and $c = 0$ then $A(\alpha) \cap A(\beta) \neq \emptyset$;

(iii) if $b < 0$ then $ax + by = a + b$ passes through $S$;

(iii) if $b > 0$ and $c > 1$ then $ax + by = a + b - 1$ passes through $S$.

17. Let $\alpha, \beta, a, b, c, d, S$ be as in $\# 16$. Then:

(i) there are integers $u$ and $v$ such that

$$a(u + \frac{d}{\alpha}) = -b(v + \frac{d}{\beta})$$

(ii) if $w_n = \frac{nd}{b}(u + \frac{d}{\alpha}) - \left[ \frac{nd}{b}(u + \frac{d}{\alpha}) \right],

x_n = \frac{b}{d}w_n, y_n = -\frac{a}{d}w_n$ then \{ $w_1, w_2, \ldots$ \} is dense in $[0, 1]$ while the points $(x_n, y_n)$ are dense on the line segment joining $(0, 0)$ to $(\frac{b}{d}, -\frac{a}{d})$;

(iii) if $c \neq 0$ and $q$ is a fixed integer there are integers $t, s, u_1, v_1$ such that $dt + sc = q$

and $au_1 + bv_1 = dt$;

(iv) if $x_{nm} = x_n + \frac{mb}{d} + u_1 + \frac{s}{\alpha},

y_{nm} = y_n - \frac{ma}{d} + v_1 + \frac{s}{\beta}$ then $(x_{nm}, y_{nm})$ is always a point on the line $ax + by = q$;
v) the points \((x_{nm}, y_{nm})\) are dense on \(ax + by = q\);

vi) if either \(b < 0\), \(c \neq 0\) or \(b > 0\), \(c > 1\) then there are infinitely many points \((x_{nm}, y_{nm})\) in \(S\);

vii) if \(b < 0\) or if \(b > 0\), \(c > 1\) then \(A(\alpha) \cap A(\beta) \neq \emptyset\).

18. If \(1, \frac{1}{\alpha}, \frac{1}{\beta}\) are rationally independent (i.e. if there does not exist a triple \(a, b, c\) of integers not all zero such that 
\[ a + b\frac{1}{\alpha} + c\frac{1}{\beta} = 0 \]
then \(A(\alpha) \cap A(\beta) \neq \emptyset\).

19. (Skolem) If \(\alpha\) and \(\beta\) are positive irrational numbers then \(A(\alpha) \cap A(\beta) = \emptyset\) if and only if there are positive integers \(a\) and \(b\) such that \(\frac{a}{\alpha} + \frac{b}{\beta} = 1\).
20. (Skolem) This special case of Uspensky's theorem (see *15) was proved by Skolem [1957].

There do not exist positive irrational numbers \( \alpha, \beta, \gamma \) such that \( A(\alpha), A(\beta), A(\gamma) \) are pairwise disjoint.

21. (Bang) If \( \alpha \) and \( \beta \) are positive irrational numbers then \( A(\alpha) \cap A(\beta) \neq \emptyset \) if and only if the line segment joining \((\alpha, 0)\) and \((0, \beta)\) passes through a lattice point.

Remarks.
The material of this chapter is drawn primarily from Skolem [1957], Bang [1957], and Graham [1963]. The interested reader might also consult Niven [1963], Connell [1959, 1960], Uspensky [1927], Graham [1973] and the references given in the 1st remark at the end of IV.

For *10, 11 see Roberts [1973].
vii The Game of Wythoff

Consider the sequence of sets (duplicate elements are permitted):

\[
\{78, 35\} \rightarrow \{70, 35\} \rightarrow \{70, 25\} \rightarrow \{50, 5\} \\
\rightarrow \{5, 5\} \rightarrow \{0, 0\}.
\]

Each element in the sequence may be obtained from the preceding one by subtracting a positive integer from one or the other of the two elements or by subtracting one and the same positive integer from each of the two elements. When a set \(\{a, b\}\) of non-negative integers arises from a set \(\{m, n\}\) in one of these three ways we say \(\{a, b\}\) is a derived set of \(\{m, n\}\). A sequence of sets, as above, in which each set is a derived set of the preceding set and which ends with \(\{0, 0\}\) is called a derived sequence. The passage
from any set to a derived set is called a move and a move to \( \{0, 0\} \) is called a winning move. If two players, A and B, start with \( \{m, n\} \) and alternately make the moves of a derived sequence, A moving first, and each desiring to make the winning move of the sequence, then we call the play resulting the game of Wythoff. We are interested in knowing the conditions under which the player moving first, A for us, can force a win for himself. Noting that \( \{m, n\} = \{n, m\} \) and assuming all integers are non-negative we may prove:

1. If A can leave any of the following pairs to B then, regardless of B's move, A can win: 

\[ \{1, 2\}, \{3, 5\}, \{4, 7\}, \{6, 10\}, \{8, 13\}, \{9, 15\}, \{11, 18\}. \]
2. If \( \{ a, b \} \) is a set of distinct non-zero integers not in the list in \#1 and if the smaller of \( a, b \) is < 12 then there is a move taking \( \{ a, b \} \) into one of the sets listed in \#1.

3. In the game of Wythoff starting with \( \{ m, n \} \), \( m \leq 18 \), \( n \leq 18 \), A can force a win for himself if and only if \( \{ m, n \} \) does not appear in the list in \#1.

4. There exists an infinite sequence of sets, of which the first 7 are those listed in \#1, such that A can always force a win for himself if and only if he starts from a set not in the sequence.

5. The sequence given in \#4 is just
\[
\left\{ \left\lfloor n \tau \right\rfloor, \left\lfloor n \tau^2 \right\rfloor \right\}, \ n \geq 1, \ \tau = \frac{1+\sqrt{5}}{2}.
\]
Remarks.

The game of Wythoff was first introduced by Wythoff [1907] as a variant of the game of Nim (see Bouton [1902]). It is discussed in Coxeter [1953] and has been generalized by Holladay [1968] and Connell [1959].
The number theoretic functions \( \tau, \sigma, \varphi \) are defined as follows:

\[
\begin{align*}
\tau(n) &= \text{number of positive integral divisors of } n = \sum_{d \mid n} 1; \\
\sigma(n) &= \text{sum of the positive integral divisors of } n = \sum_{d \mid n} d; \\
\varphi(n) &= \text{number of positive integers not exceeding } n \text{ and relatively prime to } n = \sum_{(a,n)=1} 1.
\end{align*}
\]

1. If \((a, b) = 1\) then:
   
   i) \( \tau(ab) = \tau(a) \tau(b) \);
   
   ii) \( \sigma(ab) = \sigma(a) \sigma(b) \);
   
   iii) \( \varphi(ab) = \varphi(a) \varphi(b) \).
2. If $\alpha$ is a non-negative integer and $p$ is a prime then:
   
i) $\tau(p^\alpha) = \alpha + 1$ ;
   
ii) $\sigma(p^\alpha) = \frac{p^{\alpha+1} - 1}{p - 1}$ ;
   
iii) $\varphi(p^\alpha) = p^\alpha(1 - \frac{1}{p})$ .

3. Let $n = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$. Then:
   
i) $\tau(n) = (\alpha_1 + 1) \cdots (\alpha_k + 1)$ ;
   
ii) $\sigma(n) = \prod_{j=1}^{k} \frac{p_j^{\alpha_j+1} - 1}{p_j - 1} \left( = \prod_{p|n} \frac{p^{\alpha+1} - 1}{p - 1} \right)$ ;
   
iii) $\varphi(n) = n \prod_{p|n} (1 - \frac{1}{p})$ .

4. If $\tau(n)$ is odd then $n$ is a square .

5. $\prod_{d|n} d = n^{\frac{1}{2} \tau(n)}$ .

6. $\tau(2^n - 1) \geq \tau(n)$ .

7. $\tau(2^n + 1) > \tau^*(n)$, where $\tau^*(n)$ is the number of positive odd divisors of $n$ .
8. \( \sum_{d|n} \tau^3(d) = (\sum_{d|n} \tau(d))^2 \).

9. For \( n > 0 \),
\[
\tau(1) + \tau(2) + \cdots + \tau(n) = \left[ \frac{n}{1} \right] + \left[ \frac{n}{2} \right] + \cdots + \left[ \frac{n}{n} \right] = 2 \sum_{d=1}^{\sqrt{n}} \left[ \frac{n}{d} \right] - [\sqrt{n}]^2 .
\]

10. If \( \sigma_t(n) = \sum_{d|n} d^t \) then \( \sigma_t(n) = \prod_{p|n} p^{(\alpha+1)t-1} \).

11. If \( a > 0, b > 1 \) then
\[
\frac{\sigma(a)}{a} < \frac{\sigma(ab)}{ab} \leq \frac{\sigma(a)\sigma(b)}{ab} .
\]

12. If \( a > 0, b > 0 \) then
\[
\sigma(a)\sigma(b) = \sum_{d|(a,b)} d \sigma\left( \frac{ab}{d^2} \right) .
\]

13. \( \sigma(1) + \sigma(2) + \cdots + \sigma(n) = \left[ \frac{n}{1} \right] + 2\left[ \frac{n}{2} \right] + \cdots + n\left[ \frac{n}{n} \right] .
\]

14. \( \Phi(5186) = \Phi(5187) = \Phi(5188) = 2592 . \)
15. i) For $n \geq 1$, $\varphi(n^2) = n \varphi(n)$;

ii) for $n \geq 2$, $\varphi(n) < n$;

iii) for $n \geq 3$, $\varphi(n^2) + \varphi((n+1)^2) < 2n^2$.

16. For $n > 2$ we have
\[
\sum_{\substack{m \in \mathbb{N} \mid (m,n) = 1 \\
1 \leq m \leq n}} m = \frac{1}{2} n \varphi(n).
\]

17. If $\varphi(n) \mid n$ then $n$ is of one of the forms
\[1, 2^\alpha, 2^\alpha \cdot 3^\beta.\]

18. If $a$ and $b$ are larger than 1 and $c$ is the product of the distinct prime factors of $(a, b)$ then $\varphi(ab) = \varphi(a) \varphi(b) \frac{c}{\varphi(c)}$.

19. \[
\sum_{d \mid n} \varphi(d) = n.
\]

20. \[
\sum_{d=1}^{n} \varphi(d) \left\lfloor \frac{n}{d} \right\rfloor = \frac{1}{2} n (n+1).
\]

21. \[
\sum_{n=1}^{\infty} \frac{\varphi(n) x^n}{1 - x^n} = \frac{x}{(1-x)^2}.
\]
22. The formula for \( \psi(n) \) given in \( \#3 \) implies that the number of primes is infinite.

23. (Schinzel) Let \( N_m \) be the number of solutions of the equation \( \psi(x) = m \). Then the sequence \( N_1, N_2, \ldots \) is not bounded, as can be seen from the fact that \( \psi\left( p_1 \cdots p_k \frac{1}{p_j} p_1 \cdots p_k \right) \) is independent of \( j \), \( 1 \leq j \leq k \). Here \( p_1, \ldots, p_k \) are the first \( k \) primes in their natural order.

24. Let \( n = p_1^{a_1} \cdots p_k^{a_k} \) and write \( \psi(x, n) \) for the number of positive integers not exceeding \( x \) and relatively prime to \( n \). Then:

i) (Legendre) \[ \psi(x, n) = \left[ x \right] - \sum_i \left[ \frac{x}{p_i} \right] + \sum_{i < j} \left[ \frac{x}{p_i p_j} \right] - \cdots + (-1)^k \left[ \frac{x}{p_1 \cdots p_k} \right] \;

ii) the expression for \( \psi(n) \) given in \( \#3(\#3) \) is a special case of (i).
iii) $\pi(x)$, the number of primes not exceeding $x$, satisfies:

$$\pi(x) = \pi(\sqrt{x}) - 1 + \psi(x, p_1 \ldots p_t),$$

where $p_1, \ldots, p_t$ are all the primes not exceeding $\sqrt{x}$.

25. If $\sigma(n) = 2n$, one calls $n$ a perfect number.

i) 6, 28, 496, 8128 are perfect;

ii) $2^n - 1$ prime and $n$ prime imply $2^{n-1}(2^n - 1)$ is perfect;

iii) If $n$ is even and perfect then there is a $k$ for which $n = 2^{k-1}(2^k - 1)$ and each of $k$ and $2^k - 1$ is prime;

iv) In antiquity it was often stated that every even perfect number ends in 6 or 8 and that no two consecutive even perfect numbers have the same base 10 final digit; the 1st though not the 2nd of these assertions is true;
v) \[ \sum_{d \mid n} \frac{1}{d} = 2 \text{ if and only if } n \text{ is perfect; } \]
vi) if \( n \) is odd and has no more than 2 distinct prime factors then \( n \) is not perfect.

26. Let \( H(n) \) be the harmonic mean of the divisors of \( n \); i.e. \( \frac{1}{H(n)} = \frac{1}{\sigma(n)} \sum_{d \mid n} \frac{1}{d} \). Then:

i) \( H(n) = \frac{n \tau(n)}{\sigma(n)} \) and \( H \) is multiplicative;

ii) \( H(n) > 1 \) for \( n > 1 \) and \( H(n) > 2 \) except for \( n = 1, 4, 6 \) or \( n \) prime;

iii) if \( m = 2^{n-1}(2^n - 1) \) is perfect then \( H(m) = n \);

iv) if \( n = 2^{H(n)-1}(2^{H(n)} - 1) \) is even then \( H(2^{H(n)} - 1) < 2 \);

v) (Laborde) if \( n \) is even and \( n = 2^{H(n)-1}(2^{H(n)} - 1) \) then \( n \) is perfect.

27. i) If \( f \) is a multiplicative arithmetic function, i.e. if \( f(ab) = f(a)f(b) \) for \( (a,b) = 1 \), then the function \( g \) defined by \( g(n) = \sum_{d \mid n} f(d) \) is also multiplicative.
ii) the multiplicativity of all of the following functions follows from \((i)\):
\[
\tau(n), \sigma(n), \sigma_t(n), \sigma^o(n),
\]
where \(\sigma^o(n)\) is the sum of the odd divisors of \(n\).

**Remarks.**

1. The result in \(#23\) will be found in Sierpinski [1964a].

2. As seen in \(#25(iii)\) the even perfect numbers are all of the form \(2^{n-1}(2^n-1)\) where \(2^n-1\) is prime. Primes of this form are called Mersenne primes and will be discussed in \(xix\). There are only 24 Mersenne primes known and they are for the following values of \(n\): \(2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 9539, 9679, 11213, 19937\).
It is interesting to note that until 1952 the largest known prime was \(2^{127}-1\), a number of 39 digits, while the largest known prime today is \(2^{19937}-1\), a number of 6012 digits. There are only the 24 even perfect numbers corresponding to these Mersenne primes known and it is not known if odd perfect numbers exist. See McCarthy [1957]. The result of #25(vi) may, however, be considerably improved. Also it has been shown that no odd perfect number < \(10^{50}\) exists (see Hagis [1973]).

3. The main result in #26 is due to Laborde [1955].
1. Let $p$ be a prime. Then:
   i) $p \mid (m+n)^p - (m^p + n^p)$;
   ii) $p \mid m^p - m$ if and only if $p \mid (m+1)^p - (m+1)$;
   iii) (Fermat's "little" theorem)
       $p \mid m^p - m$ for all $m \geq 1$.

2. For $p$ a prime,
   $p \mid (m_1 + \cdots + m_k)^p - (m_1^p + \cdots + m_k^p)$,
   and Fermat's little theorem is an immediate
   consequence of this.

3. When $p$ is an odd prime then:
   $p \mid m^p + n^p$ implies $p^2 \mid m^p + n^p$.

4. (Golomb) Let there be given a collection
   of beads of $n$ different colors from which we
   wish to make non-one-color necklaces of
exactly $p$, $p | n$, beads. The number $p$ is to be a prime. Then:

i) there are $n^p - n$ linear $p$ length strings of non-one-color beads;

ii) the number of distinguishable necklaces of the desired type is $\frac{n^p - n}{p}$;

iii) $n^p \equiv n \pmod{p}$ (Fermat's theorem);

iv) $n^p \equiv n \pmod{2p}$ for $p$ odd.

5. Let $n$ be an arbitrary integer larger than 1 and put $N = (n!)^2$. Then:

i) every prime factor of $N+1$ is odd and greater than $n$;

ii) $N+1 | N^m + 1$ for any positive odd integer;

iii) if $p$ is a $4k+3$ prime factor of $N+1$ then $p | N^{2k+1}$ and this contradicts Fermat's theorem;

iv) there are infinitely many $4k+1$ primes.
6. Let \( p \) be a prime and suppose \( (n, p) = 1 \).
   i) if \( na \equiv nb \pmod{p} \) then \( a \equiv b \pmod{p} \);
   ii) \( n^{p-1}(p-1)! \equiv (p-1)! \pmod{p} \);
   iii) \( n^{p-1} \equiv 1 \pmod{p} \) (Fermat's theorem).

7. Let \( a_1, \ldots, a_{\varphi(m)} \) be relatively prime to \( m \) and also be incongruent modulo \( m \) in pairs.
   Further, suppose \( (n, m) = 1 \).
   i) if \( na_i \equiv na_j \pmod{m} \) then \( i = j \);
   ii) \( n^{\varphi(m)}a_1 \cdots a_{\varphi(m)} \equiv a_1 \cdots a_{\varphi(m)} \pmod{m} \);
   iii) (Euler) \( n^{\varphi(m)} \equiv 1 \pmod{m} \) for \( (n, m) = 1 \);
   iv) Fermat's theorem is a special case of (iii).

8. When \( a \) is an odd integer
   i) \( a^{2} \equiv 1 \pmod{8} \);
   ii) \( a^{2^{\alpha-2}} \equiv 1 \pmod{2^{\alpha}} \) for \( \alpha > 2 \).
9. Define $\chi$ by:

$$
\chi(p^\alpha) = \begin{cases} 
\varphi(p^\alpha) & \text{for } p \text{ an odd prime} \\
\frac{1}{2}\varphi(p^\alpha) & \text{for } p = 2, 0 \leq \alpha \leq 2 \\
\frac{1}{2}\varphi(p^\alpha) & \text{for } p = 2, \alpha > 2.
\end{cases}
$$

$$
\chi(p_1^{\alpha_1} \cdots p_k^{\alpha_k}) = \text{lcm} \{ \chi(p_1^{\alpha_1}), \ldots, \chi(p_k^{\alpha_k}) \}.
$$

For $m > 1$, $m$ odd, $(a, m) = 1$:

i) \( a^{\chi(m)} \equiv 1 \pmod{m} \);

ii) $m$ a prime implies \( \varphi(m) \mid m - 1 \);

iii) \( \varphi(m) \mid m - 1 \) implies \( \chi(m) \mid m - 1 \);

iv) \( \chi(m) \mid m - 1 \) implies \( 2^{m-1} \equiv 1 \pmod{m} \);

v) the converses of (iii) and (iv) are false as can be seen by taking $m = 561$ and $m = 341$.

(No example of $\varphi(m) \mid m - 1$ for composite $m$ is known.)

10. If $p$ is an odd prime then

$$
2^{p-1} \equiv 1 \pmod{p} \text{ or } 2^{p-1} \equiv -1 \pmod{p}.
$$
11. i) Suppose \( n > 6, n = ab \) with \( 1 < a < b \). Then:
   a) \( b < n - 3 \);
   b) if \( a = b \) then \( 2a < n - 3 \);
   ii) if \( n \) is composite and \( \geq 6 \) then \( \frac{(n-2)!}{n} \) is an even integer.

12. Suppose \( (a, m) = 1 \) and \( p \) is a prime. Then:
   i) \( ax \equiv 1 \pmod{m} \) has a unique solution modulo \( m \);
   ii) if, in (i), \( a \not\equiv \pm 1 \pmod{m} \) then \( x \not\equiv \pm 1 \pmod{m} \) and \( x \not\equiv a \pmod{m} \);
   iii) \( 2 \cdot 3 \cdots (p-2) \equiv 1 \pmod{p} \);
   iv) (Wilson's theorem) \( (p-1)! \equiv -1 \pmod{p} \);
   v) for \( n > 1 \), \( n \) is a prime if and only if \( n \mid (n-1)! + 1 \).

13. Wilson's theorem may be used to show that the congruence \( x^2 + 1 \equiv 0 \pmod{p} \) is solvable when \( p \) is a \( 4k+1 \) prime.
14. Let \( p \) be an odd prime and mark \( p \) points uniformly spaced on a circle. Let \( T \) and \( R \) be the sets of all \( p \)-gons and the regular \( p \)-gons respectively. Then:

i) the cardinality of \( T \) is \( \frac{1}{2}(p-1)! \);

ii) the cardinality of \( R \) is \( \frac{1}{2}(p-1) \);

iii) the cardinality of \( T-R \) is divisible by \( p \);

iv) \( (p-1)! \equiv -1 \pmod{p} \) (Wilson's theorem).

15. (Clément) Let \( m,n \) be positive integers.

i) \( (m+n-1)! \equiv (-1)^n n!(m-1)! \pmod{m+n} \);

ii) \( (n!)^2((m-1)!+1)+(n-1)(n-1)!m \equiv n!((-1)^n(m+n-1)!+1) \pmod{m+n} \);

iii) If \( p \) and \( p+k \) are odd primes then 

\( (p,k)=1, k \) is even, and

\( (k!)^2((p-1)!+1)+(k!-1)(k-1)! \equiv 0 \pmod{p(p+k)} \);

iv) the converse of (iii) may be false even though \( (p,k)=1 \) and \( k \) is even.
v) the converse of (iii) is true when $p$ and $p+k$ are prime to $k$; 

vi) let $n$ be an odd integer $>1$; then

$$4((n-1)!+1)+n \equiv 0 \pmod{n(n+2)}$$

if and only if $n$ and $n+2$ are odd primes.

16. Let $(a, m) = 1$ and suppose $s$ is the smallest integer $t$ for which $a^t \equiv 1 \pmod{m}$. Then if $a^n \equiv 1 \pmod{m}$, $s | n$.

17. i) $a^{m-1} \equiv 1 \pmod{m}$ for all $a$, $(a, m) = 1$, does not imply $m$ is prime, as one can see with $m = 561$; 

ii) if $a^{m-1} \equiv 1 \pmod{m}$ for some $a$ such that $a^t \not\equiv 1 \pmod{m}$ for any $t$, $0 < t < m-1$, $t | m-1$, then $m$ is prime.

18. $2^p \equiv 1 \pmod{p^2}$ for the primes $p = 1093$ and $p = 3511$. 
19. A composite \( n \) which divides \( 2^n - 2 \) is called a pseudoprime.

i) 341, 561, and 161038 are pseudoprimes;

ii) every composite Fermat number
\( \mathcal{F}_n = 2^{2^n} + 1, \ n \geq 0 \), is a pseudoprime;

iii) if \( n \) is an odd pseudoprime then \( 2^n - 1 \)

is a larger one;

(iv) (Erdős [1950]) if \( n = \frac{2^{2p} - 1}{3} \), where \( p \) is a prime \( > 3 \), then \( n \) is a pseudoprime;

v) there are infinitely many odd pseudoprimes.

20. Let \( F \) and \( G \) be polynomials in \( n \) variables with integral coefficients. We say \( F \) is congruent to \( G \) modulo \( p \), and write \( F \equiv G \pmod{p} \), if respective coefficients in \( F \) and \( G \) are congruent modulo \( p \). We say \( F \) is equivalent to \( G \) modulo \( p \), and write \( F \sim G \pmod{p} \), if for all integral choices \( c_1, \ldots, c_n \) it is true that
\[ F(c_1, \ldots, c_n) \equiv G(c_1, \ldots, c_n) \pmod{p}. \]
we say that $F$ is reduced mod $p$ if no variable appears in $F$ to a power larger than $p-1$. Here $p$ will always be a prime.

i) a) $F \equiv G \pmod{p}$ implies $F \sim G \pmod{p}$;
   b) the converse of (a) is false;
   c) every polynomial $F$ is equivalent mod $p$ to a reduced polynomial $F^*$, where $\deg F^* \leq \deg F$;
   d) if $F$ and $G$ are reduced polynomials in one variable then $F \sim G \pmod{p}$ implies $F \equiv G \pmod{p}$;
   e) if $F$ and $G$ are reduced polynomials in any finite number of variables the implication in (d) is valid;

ii) let $F$ be a polynomial in $n$ variables and suppose the congruence $F(x_1, \ldots, x_n) \equiv 0 \pmod{p}$ has exactly one solution $(x_1, \ldots, x_n) = (a_1, \ldots, a_n)$ modulo $p$ (i.e. the components are taken modulo $p$).
Define $H$ and $G$ by:

$$H(x_1, \ldots, x_n) = \prod_{i=1}^{n} \left( 1 - (x_i - a_i)^{p-1} \right),$$

$$G(x_1, \ldots, x_n) = 1 - F^{p-1}(x_1, \ldots, x_n).$$

Then:

1. $H(a_1, \ldots, a_n) \equiv 1 \pmod{p}$;
2. If for some $j, 1 \leq j \leq n, x_j \not\equiv a_j \pmod{p}$ then $H(x_1, \ldots, x_n) \equiv 0 \pmod{p}$;
3. $H \equiv G^* \pmod{p}$, where $G^*$ is the reduced form of $G$;
4. $\deg H = n(p-1) = \deg G^* \leq \deg G = (\deg F)(p-1)$ so $n \leq \deg F$;

(iii) (Chevalley) if $F$ is a polynomial in $n$ variables with degree smaller than $n$ then the congruence $F(x_1, \ldots, x_n) \equiv 0 \pmod{p}$ may not have exactly one solution;

(iv) if $F$ is a non-constant form in $n$ variables (i.e. if all the terms of $F$ are of the same degree)
and if \( \deg F < n \) then \( F(x_1, \ldots, x_n) \equiv 0 \pmod{p} \)
has a non-trivial solution (i.e., a solution
with not all \( x_j \equiv 0 \pmod{p} \));

v) (Warning) let \( F \) be a polynomial in \( n \)
variables of degree \( r \), where \( r < n \), and let \( p \)
be a prime. Suppose \( F(x_1, \ldots, x_n) \equiv 0 \pmod{p} \)
has exactly \( s \) solutions, say \((a_1, \ldots, a_s)\), \n\( 1 \leq i \leq s \). Then:

\( a) \) if \( \mathcal{H}(x_1, \ldots, x_n) = 1 - F^{p-1}(x_1, \ldots, x_n) \)
then the reduced form of \( \mathcal{H} \), say \( \mathcal{H}^* \), is
\( \mathcal{H}^*(x_1, \ldots, x_n) = \prod_{i=1}^{s} \prod_{j=1}^{n} (1 - (x_j - a_j)^{p-1}) \);

\( b) \) the highest degree term in \( \mathcal{H}^* \) is
\((-1)^n s \prod_{i=1}^{s} x_i^{p-1} \ldots x_n^{p-1} \);

\( c) \) since \( r < n \) and degree \( \mathcal{H} < r (p-1) \)
it must be true that \( p | s \);

\( d) \) if \( F \) is a polynomial in \( n \) variables
with \( \deg F < n \) then the number of solutions
of \( F(x_1, \ldots, x_n) \equiv 0 \pmod{p} \) is divisible by \( p \)
vi) By careful examination of \((v-a)\) one may prove, as in \((v)\), the following theorem.

If \(F\) is a polynomial in \(n\) variables with \(\deg F < n\) and \((a_1^{(i)}, \ldots, a_n^{(i)})\), \(1 \leq i \leq s\), are all the solutions of \(F(x_1, \ldots, x_n) \equiv 0 \pmod{p}\) then for each pair \(j, k\) \((1 \leq j, k \leq n, 0 \leq k < p-2)\) the prime \(p\) divides the sum \(\sum_{i=1}^{s} (a_j^{(i)})^k\).

vii) Let \(F_1, \ldots, F_m\) be polynomials in \(n\) variables with respective degrees \(r_1, \ldots, r_m\) \(r_1 + \cdots + r_m < n\). Suppose, further, the system

\[(\star) \ F_i(x_1, \ldots, x_n) \equiv 0 \pmod{p}, \ldots, F_m(x_1, \ldots, x_n) \equiv 0 \pmod{p}\]

has at least one solution. Then:

a) the system has at least two solutions;

b) the number of solutions of \((\star)\) is divisible by \(p\).
Remarks.

1. The argument in #4 was given by Golomb [1956].

2. In respect to #9(iii), as we observed, no example of a composite $m$ for which $\varphi(m) \mid m-1$ is known. However in 1932 Lehmer showed that such an $m$ would have to be odd, squarefree, and have at least 7 prime factors. The 7 has since been raised to 11. If, in addition, one assumes 3 divides $m$ then $m$ must have at least 212 prime factors. (See Lieuwens [1970].)

3. Gauss in his Disquisitiones Arithmeticae had the following to say about Wilson's theorem (see #12, 14).

   It was first published by Waring and attributed to Wilson... But neither of them was able to prove the theorem,
and Waring confessed that the demonstration was made more difficult because no notation can be devised to express a prime number. But in our opinion truths of this kind should be drawn from the ideas involved rather than from notation.

The proof of Wilson's theorem in \#14 goes back to the Danish mathematician J. Peterson who proved it in this way in 1872. The English mathematician A. Cayley, apparently independently, gave a similar proof about 10 years later. (See Dickson's History V. I pp. 75-6.)

4. The result in \#15(vi) is due to Clement [1949] and that in \#15(iii) to Tkačev and Shinzel (see MR 32 #1159, erratum p. 1754). There has been considerable work on related problems (see LeVeque [1974] V. I A50).
5. Primes $p$ with $2^{p-1} \equiv 1 \pmod{p^2}$, see *18, are of interest in connection with Fermat's last theorem (do there exist integers $x, y, z$ with $xyz \neq 0$ and $x^n + y^n = z^n$ for $n > 2$) since in 1907 Wieferich showed that if $p$ is a prime and $x^p + y^p = z^p$, $xyz \neq 0$, then $p$ satisfies this congruence. For more recent information and further references see Brillhart, Tomascia, Weinberger [1971].

6. For further information on pseudo-primes see Beeger [1951], LeVeque [1974 V.1 A18], and Rotkiewicz [1972].

7. Further extensions of the Chevalley-Warning theorems, see *20, may be found in Borevich, Schafarevich [1966].
$x$ Divisibility Criteria

Let $S_k(n)$ be the base $k$ digit sum of $n$.

1. i) $3 \mid n - S_{10}(n)$ and, therefore,
   
   $3 \mid n$ if and only if $3 \mid S_{10}(n)$;

   ii) $9 \mid n - S_{10}(n)$ and, therefore,
      
      $9 \mid n$ if and only if $9 \mid S_{10}(n)$;

   iii) suppose $d \mid k - 1$; then $d \mid n - S_k(n)$, and, therefore, $d \mid n$ if and only if $d \mid S_k(n)$.

2. (Alvis) Let $p$ be a prime larger than 7. Then:
   
   i) $(6, S_7(p)) = 1$;

   ii) the smallest $p$ with composite $S_7(p)$ is 4801;

   iii) for $p < 100000$ the only possible composite value of $S_7(p)$ is 25.

3. Let $E_k(n)$ ($O_k(n)$) be the sum of the digits of the even (odd) powers of $k$ in the base $k$
expansion of \( n \). Then:

i) \( 11 \mid n - (E_{10}(n) - O_{10}(n)) \) and, therefore,

\[ 11 \mid n \text{ if and only if } 11 \mid E_{10}(n) - O_{10}(n) \];

ii) suppose \( d \mid k+1 \); then \( d \mid n - (E_k(n) - O_k(n)) \) and, therefore, \( d \mid n \) if and only if \( d \mid E_k(n) - O_k(n) \).

4. Given \( n \) write \( Q(n), R(n) \) for the quotient and remainder obtained when one divides \( n \) by 1000. Thus \( n = 1000Q(n) + R(n) \), \( 0 \leq R(n) < 1000 \). Then:

i) \( Q(n) = \left\lfloor \frac{n}{1000} \right\rfloor \), \( R(n) = n - 1000Q(n) \);

ii) if \( c = 7, 11 \), or 13 then \( c \mid n \) if and only if \( c \mid Q(n) - R(n) \);

iii) the above leads to a workable divisibility criterion for determining the divisibility of a number exceeding 1000 by 7, 11, or 13.
5. Let \( T_k(n) = \frac{n - S_k(n)}{k - 1} \), where \( S_k(n) \) is as above. Then:

i) \( T_k(n) \) is an integer;

ii) if \( k \) is prime then \( T_k(n) \) is the highest power of \( k \) dividing \( n! \);

iii) the highest power of 2 in \( n! \) is \( n - \nu \), where \( \nu \) is the number of 1's in the base 2 expansion of \( n \);

iv) if \( k \) is a prime and \( n = a_0 + a_1 k + \ldots + a_s k^s \), \( 0 \leq a_j < k \), then \( k \mid \frac{n!}{(-k)^{T_k(n)}} - a_0! \cdots a_s! \).
11 Squares

1. The following equalities are special cases of a simple algebraic identity.

\[ 3^2 + 4^2 = 5^2 \]
\[ 10^2 + 11^2 + 12^2 = 13^2 + 14^2 \]
\[ 21^2 + 22^2 + 23^2 + 24^2 = 25^2 + 26^2 + 27^2 \]
\[ 36^2 + 37^2 + 38^2 + 39^2 + 40^2 = 41^2 + 42^2 + 43^2 + 44^2. \]

2. (Sprague)

i) 128 is not a sum of unequal squares;

ii) if \( 129 \leq n \leq 192 \) then \( n \) is a sum of unequal squares all \( \leq 10^2 \);

iii) if \( 129 \leq n \leq 256 \) (\( = 1^2 + \cdots + 10^2 - 129 \)) then \( n \) is a sum of unequal squares all \( \leq 10^2 \);

iv) if \( 129 \leq n \leq 256 + 11^2 \) then \( n \) is a sum of unequal squares all \( \leq 11^2 \);

v) if \( 129 \leq n \leq 256 + 11^2 + 12^2 \) then \( n \) is a sum of unequal squares all \( \leq 12^2 \);
vi) every integer larger than 128 is a sum of unequal squares.

3. Let $C$ be the unit circle with center at the origin and let $L_\lambda$ be the straight line of slope $\lambda$ passing through $(-1,0)$. Further, let $C'$ be $C$ with the point $(-1,0)$ removed and let $P_\lambda$ be the intersection of $C'$ and $L_\lambda$. Then:

i) as $\lambda$ runs over all rational numbers the point $P_\lambda$ runs in a one to one fashion over all points of $C'$ both coordinates of which are rational; in fact, the correspondence is

$$\lambda \leftrightarrow \left( \frac{1-\lambda^2}{1+\lambda^2}, \frac{2\lambda}{1+\lambda^2} \right) ;$$

ii) if $x, y, z$ are non-zero integers with gcd unity and if $x^2 + y^2 = z^2$ then there exist relatively prime integers $u, v$ of opposite parity, such that either

$$x = v^2 - u^2, \ y = 2uv, \ z = u^2 + v^2$$

or the same expressions with $x$ and $y$ interchanged.
4. The sum of 2 odd squares is never a square.

5. (Thue) Suppose \( p \) is a prime not dividing \( a \) and \( \mathbb{A} = \{(m,n) \mid 0 \leq m < \sqrt{p}, 0 \leq n < \sqrt{p}\} \). Then:

i) there are distinct elements of \( \mathbb{A} \), say \((m,n)\) and \((m',n')\), such that \( am + n \equiv am' + n' \pmod{p} \); 

ii) there is an element of \( \mathbb{A} \), say \((x,y)\) such that \( xy \neq 0 \) and either \( ay \equiv x \pmod{p} \) or \( ay \equiv -x \pmod{p} \), i.e. there exist \( x, y \) such that \( 0 < x < \sqrt{p} \), \( 0 < y < \sqrt{p} \), \( ay \equiv \pm x \pmod{p} \).

6. (Generalization - Vinogradoff, Scholz - Shoenberg)

i) If \( (a,m) = 1 \) and \( e,f \) are integers larger than 1 satisfying \( e \leq m < ef \), \( f \leq m < ef \) then there exist \( x, y \) such that \( 0 < x < e \), \( 0 < y < f \), \( ay \equiv \pm x \pmod{m} \);

ii) \( \#5(ii) \) is a special case of (i).
7. (Fermat) As we know from $1x \equiv 13$, when $p$ is a $4k+1$ prime, there is an $a$ such that $a^2 + 1 \equiv 0 \pmod{p}$; selecting such an $a$ and then choosing $x, y$ as in \#5(ii) we conclude $x^2 + y^2 = p$; thus every $4k+1$ prime is the sum of two squares.

8. i) If $p$ is a $4k+3$ prime then $p = x^2 + y^2$ is not solvable in integers $x, y$;
   ii) if $p$ is an odd prime then $p$ is representable as a sum of two squares if and only if $p \equiv 1 \pmod{4}$.

9. Let $p$ be an odd prime and suppose $(a, b) = 1$, $a^2 + b^2 \equiv 0 \pmod{p}$. Then:
   i) for all $u, v$
      $$(au + bv)^2 + (av - bu)^2 \equiv 0 \pmod{p}$$
   ii) $x^2 + 1 \equiv 0 \pmod{p}$ is solvable;
iii) all odd divisors of a sum of two relatively prime squares are of the form $4k+1$.

10. i) The result in §9(iii) guarantees the existence of infinitely many $4k+1$ primes;
   ii) all prime factors of the Fermat numbers $F_n = 2^{2^n} + 1$ are of the form $4k+1$ and from this we may also conclude the existence of infinitely many primes of the form $4k+1$.

11. i) The set of positive integers which are sums of two squares is closed under multiplication as can be seen by multiplying out the left side of the congruence in §9(i) and then factoring;
   ii) the formulae of §3(ii) may be obtained from the identity implicit in (i).
12. Let the canonical prime factorization of \( n \) be given by \( n = 2^\alpha p_1^{\alpha_1} \cdots p_s^{\alpha_s} q_1^{\beta_1} \cdots q_t^{\beta_t} \), where the \( p_i \) are \( 4k+1 \) primes and the \( q_i \) are \( 4k+3 \) primes. Then:

i) If \( n \) is representable as the sum of 2 squares then all \( \beta_j, 1 \leq j \leq t \), are even;

ii) If all \( \beta_j, 1 \leq j \leq t \), are even each of \( 2^\alpha \), \( p_1^{\alpha_1} \), \( \cdots \), \( p_s^{\alpha_s} \), \( q_1^{\beta_1} \), \( \cdots \), \( q_t^{\beta_t} \) is a sum of 2 squares and, therefore, \( n \) is a sum of 2 squares;

iii) An integer is the sum of 2 squares if and only if its canonical prime factorization contains no \( 4k+3 \) prime to an odd power.

13. We write \( n = \mathbf{4} \) if \( n \) is representable as a sum of 4 squares. Thus \( 25 = \mathbf{4} \) and \( 30 = \mathbf{4} \) since \( 25 = 0^2 + 0^2 + 0^2 + 5^2 \), \( 30 = 1^2 + 2^2 + 3^2 + 4^2 \). The product of two sums of 4 squares is itself a sum of 4 squares, as can be seen by verifying the identity:
14. Let $p$ be an odd prime. Then:

i) if $A = \{ n^2 | 0 \leq n \leq \frac{p-1}{2} \}$, $B = \{ -1 - m^2 | 0 \leq m \leq \frac{p-1}{2} \}$
then there is an element of $A$ which is congruent modulo $p$ to an element of $B$;

ii) there exists an $s$, $0 < s < p$, such that
$s p = a_1^2 + a_2^2 + a_3^2 + a_4^2$, for suitable $a_1, a_2, a_3, a_4$;

iii) for $s$ and the $a_j$ in (ii), if $s > 1$ there exist $A_1, A_2, A_3, A_4$ such that $a_j \equiv A_j \pmod{s}$, 
$-\frac{1}{2} s < A_j \leq \frac{1}{2} s$, $1 \leq j \leq 4$, and, for suitable $r$,
$0 < r < s$, $rs = A_1^2 + A_2^2 + A_3^2 + A_4^2$;

iv) for $r$ and $s$ as in (ii) or (iii), $rs^2 p = 4$, where
the summands on the right are all congruent to $0$ modulo $s^2$ and, therefore, $rp = 4$;

v) $p = 4$;

vi) every positive integer may be represented as a sum of 4 squares.
15. A triple of integers \( x, y, z \) for which \( x^2 + y^2 = z^2 \) is called a Pythagorean triple. When the integers have greatest common divisor 1 we call the triple primitive. A triangle whose side lengths form such a triple is called a Pythagorean triangle. It is clear that all Pythagorean triples are integral multiples of primitive triples. Define the three matrices \( U, A, D \) by:

\[
U = \begin{pmatrix} 1 & 2 & 2 \\ -2 & -1 & -2 \\ 2 & 2 & 3 \end{pmatrix}, \quad A = \begin{pmatrix} 1 & 2 & 2 \\ 2 & 1 & 2 \\ 2 & 2 & 3 \end{pmatrix}, \quad D = \begin{pmatrix} -1 & -2 & -2 \\ 2 & 1 & 2 \\ 2 & 2 & 3 \end{pmatrix}.
\]

Show that \( (x', y', z') \) is a primitive Pythagorean triple if and only if \( (x', y', z') = (3, 4, 5)A \) where \( A \) is a finite product of matrices each factor of which is one of \( U, A, D \). I.e. show that every Pythagorean triple is in the following array where the lines leading to the right from any triple correspond to applying to that triple either the matrix \( U \) (for up), \( A \) (for across) or \( D \) (for down).
Remarks.

1. Implicit in the solution of \#11 is an identity showing that the product of two sums of 2 squares is itself a sum of 2 squares. In \#13 there is an identity showing the same thing for the product of two numbers each of which is a sum of 4 squares. There is also an 8 square identity, though, as Hurwitz first proved in 1898, there can be no such identity for values of \( n \) other than \( n = 1, 2, 4, 8 \). (See Curtis [1963].) Dickson [1919] cites Degen as having been the first to give (in 1818) such an 8 square identity. Coxeter [1946] formulates the identity as follows:

\[
\left( a_0^2 + a_1^2 + \cdots + a_7^2 \right) \left( b_0^2 + b_1^2 + \cdots + b_7^2 \right) = \left( a_0 b_0 - a_1 b_1 - a_2 b_2 - \cdots - a_7 b_7 \right)^2 + \sum (a_0 b_1 + a_1 b_0 + a_2 b_4 + a_3 b_7 - a_4 b_2 + a_5 b_6 - a_6 b_5 - a_7 b_3)^2,
\]

where the \( \sum \) implies summation of seven squares given by cyclic permutation of the suffix numbers \( 1, 2, 3, 4, 5, 6, 7 \) leaving 0 unchanged.
2. For a number of other interesting results concerning sums of squares see Pall [1933], Taussky [1966, 1970, 1971], Zassenhaus, Eichhorn [1966], and the references at the end of xv.

3. As we showed in #2 (following Sprague [1947-9 (6)]) the largest integer not the sum of unequal squares is 128. (See also Dressler [1972, 1973].) A recent computer proof (see Dressler, Parker [1974]) has been given to show that 12,758 is the largest integer not the sum of unequal cubes. That a similar largest integer exists for $k^5$ powers is proved in XII.

4. The result of #6 will be found in Scholz, Shoenberg [1966].

5. The beautiful display of all Pythagorean triples is due to Hall [1970].
xii Sums of Powers

1. (Tarry) If $b_1^t + \cdots + b_n^t = c_1^t + \cdots + c_n^t$ for all $t$ satisfying $0 \leq t \leq m$, we write
   $$b_1, \ldots, b_n \equiv c_1, \ldots, c_n.$$
   For example, $1, 4, 6, 7 \equiv 2, 3, 5, 8$ since
   $$1^0 + 4^0 + 6^0 + 7^0 = 2^0 + 3^0 + 5^0 + 8^0, \quad 1^4 + 4^4 + 6^4 + 7^4 = 2^4 + 3^4 + 5^4 + 8^4.$$

   i) If $b_1, \ldots, b_n \equiv c_1, \ldots, c_n$ then for all $h$,
   $$b_1, \ldots, b_n, c_1 + h, \ldots, c_n + h \equiv c_1, \ldots, c_n, b_1 + h, \ldots, b_n + h;$$

   ii) $b_1, \ldots, b_n \equiv c_1, \ldots, c_n$ if and only if for all $x$
   $$(b_1 + x)^m + \cdots + (b_n + x)^m = (c_1 + x)^m + \cdots + (c_n + x)^m;$$

   iii) for every positive integer $m$ there exists a positive integer $n$ and integers $b_1, \ldots, b_n, c_1, \ldots, c_n$ such that $b_1, \ldots, b_n \equiv c_1, \ldots, c_n$.

2. Define a sequence $a_0, a_1, a_2, \ldots$ by:

$$a_n = \begin{cases} 
0 & \text{if the base 2 representation of } n \\
1 & \text{if the base 2 representation of } n \\
\text{has an even digit sum;} \\
1 & \text{otherwise.}
\end{cases}$$
using #1, starting with 1 \equiv 2, and taking h successively equal to 2, 2^2, 2^3, ... one obtains

1, 4 \equiv 2, 3

1, 4, 6, 7 \equiv 2, 3, 5, 8

1, 4, 6, 7, 10, 11, 13, 16 \equiv 2, 3, 5, 8, 9, 12, 14, 15

1, 4, 6, 7, 10, 11, 13, 16, 18, 19, 21, 24, 25, 28, 30, 31 \equiv 4

2, 3, 5, 8, 9, 12, 14, 15, 17, 20, 22, 23, 26, 27, 29, 32;

and, in general,

\[ \sum_{n=1}^{k+1} (1 - a_{n-1}) n^t = \sum_{n=1}^{k+1} a_{n-1} n^t, \quad 1 \leq t \leq k. \]

3. i) With the \( a_n \) as in #2 and arbitrary integers \( r \) and \( s \),

\[ \sum_{n=1}^{k+1} (1 - a_{n-1})(rn+s)^t = \sum_{n=1}^{k+1} a_{n-1}(rn+s)^t \] for \( 1 \leq t \leq k; \)

ii) In (i) we may replace \( (rn+s) \) by \( P(n) \), where \( P \) is any polynomial of degree not exceeding \( k \).
4. (i) The odd integers from 1 to $2^{k+2} - 1$ inclusive may be split into two disjoint equinumerous classes 
$\{ b_1, \ldots, b_{2^k} \}, \{ b_{2^k+1}, \ldots, b_{2^{k+1}} \}$ so that for all $x$
$$(b_1 + x)^k + \cdots + (b_{2^k} + x)^k = (b_{2^k+1} + x)^k + \cdots + (b_{2^{k+1}} + x)^k;$$
(ii) for all the $b_j$ of (i) there exist even integers $d_1, \ldots, d_k$ so that no two of the $k \cdot 2^{k+1}$ numbers
$b_j + d_i$ are equal, where $1 \leq j \leq 2^{k+1}, 1 \leq i \leq k$;
(iii) let $b_j$ and $d_i$ be as in (i) $\&$ (ii) and define $L_i, R_i, 1 \leq i \leq k$, by:
$$L_i = (x + d_i + b_1)^k + \cdots + (x + d_i + b_{2^k})^k$$
$$R_i = (x + d_i + b_{2^k+1})^k + \cdots + (x + d_i + b_{2^{k+1}})^k;$$
then $L_i = R_i$ for each $i, 1 \leq i \leq k$, and, further, the $2^k$ products $U_1 \ldots U_k$, where each $U_i$ is
either $L_i$ or $R_i$, are equal;
(iv) each of the products $U_1 \ldots U_k$ in (iii) is a sum of $k \cdot 2^6$ powers of terms of the form
$$(x + d_i + b_i) \ldots (x + d_k + b_k);$$ each $i_j$ satisfies
$1 \leq i_j \leq 2^{k+1};$
further, for \( x \) sufficiently large and even, all of these terms are odd and distinct from each other;

vi) let \( b_j, c_i, x \) be as in (i) - (iv), and put \( s = L_1 \cdots L_k \); then \( s \) may be written as a sum of odd \( k^{t_5} \) powers in \( 2^k \) ways, no two of which share a common summand.

5. Let \( s \) be a number having \( 2^k - 1 \) completely distinct representations as a sum of odd \( k^{t_5} \) powers, and let these sums of odd \( k^{t_5} \) powers be \( S_1, \ldots, S_{2^k - 1} \).

i) For each \( t \), \( 0 \leq t \leq 2^k \), the number \( ts \) is a sum of odd \( k^{t_5} \) powers;

ii) if the base \( 2^k \) representation of the positive integer \( m \) is given by

\[
m = t_0 + t_1 \cdot 2^k + t_2 \cdot 2^{2k} + \cdots, \quad 0 \leq t_i \leq 2^k,
\]

then \( ms = t_0 s + t_1 s \cdot 2^k + t_2 s \cdot 2^{2k} + \cdots \) is a sum of \( k^{t_5} \) powers;
iii) in (ii) in the representation of ms as a sum of $k^{t6}$ powers no two summands are equal;

iv) given a positive integer $k$ there is always a positive integer $s$ such that all positive integer multiples of $s$ are sums of unequal $k^{t6}$ powers.

6. Setting $S_r = s^k + (s+1)^k + \cdots + (rs+1)^k$, $0 \leq r < s$, where $s$ is as in #5(iv), we see that every $S_r$ is a sum of unequal $k^{t6}$ powers, and, consequently, since every $s^{2k+1} > S_r \equiv r \pmod{s}$ and every integer $\geq s^{2k+1}$ may be written in the form $ms + S_r$, we conclude:

(Sprague) Given a positive integer $k$ there is a positive integer $N$ ($= s^{2k+1}$) for which all larger integers are sums of unequal $k^{t6}$ powers; i.e. for each $k$ all sufficiently large integers are representable as a sum of unequal $k^{t6}$ powers.
Remarks.
The results in #1-3 go back to Prouhet [1851] and have been generalized considerably in recent years - see Lehmer [1947], Roberts [1964], Wright [1959]. The results in #4-6 are from Sprague [1947-9 (6)]. Further information about equal sums of like powers, see #2, may be found in Gloden [1944], Lander, Parkin, Selfridge [1967].
Continued Fractions

The sum of the products obtained from the product $1 \cdot x_0 \cdot x_1 \cdot \cdots \cdot x_n$ by omitting zero or more disjoint pairs of consecutive factors $x_j x_{j+1}$ from the product is denoted by $E(x_0, \cdots, x_n)$. This quantity, as a function of the $x_j$, is called the Euler bracket function.

One sees immediately that:

$E(x_0) = x_0$;
$E(x_0, x_1) = x_0 x_1 + 1$;
$E(x_0, x_1, x_2) = x_0 x_1 x_2 + x_0 + x_2$;
$E(x_0, x_1, x_2, x_3) = x_0 x_1 x_2 x_3 + x_0 x_1 + x_0 x_2 + x_2 x_3 + 1$;
$E(x_0, x_1, x_2, x_3, x_4) = x_0 x_1 x_2 x_3 x_4 + x_0 x_1 x_2 + x_0 x_1 x_4 + x_0 x_3 x_4 + x_0 + x_2 + x_4$.

The number of summands appearing in $E(x_0, \cdots, x_n)$ is denoted by $E_{n+1}$. Thus
\[ E_1 = 1 \; \]
\[ E_2 = 2 \; \]
\[ E_3 = 3 \; \]
\[ E_4 = 5 \; \]
\[ E_5 = 8 \; \]

1. Suppose \( n \geq 0 \). Then (providing in (v), (vi), (vii) the presence of an \( x_{n+1} \) or \( x_{n-1} \) in \( E(\cdots) \) is interpreted as making that bracket equal to 1):

i) \( E(x_0, \cdots, x_n) = E(x_n, \cdots, x_0) \);

ii) for \( n \geq 1 \),
\[ E(x_0, \cdots, x_{n+1}) = x_{n+1} E(x_0, \cdots, x_n) + E(x_0, \cdots, x_{n+1}) \; \]

iii) for \( n \geq 2 \),
\[ E(x_0, \cdots, x_n) E(x_{i_1}, \cdots, x_{i_{n-1}}) E(x_{i_1}, \cdots, x_{i_{n-1}}) = (-1)^{n-1} \; \]

iv) for \( n \geq 3 \),
\[ E(x_0, \cdots, x_n) E(x_{i_1}, \cdots, x_{i_{n-2}}) E(x_{i_1}, \cdots, x_{i_{n-2}}) E(x_{i_1}, \cdots, x_{i_{n-2}}) = (-1)^n x_n \; \]
v) for $0 < s < t < n$,

$$E(x_0, \ldots, x_n)E(x_s, \ldots, x_t) - E(x_0, \ldots, x_s)E(x_s, \ldots, x_t)$$

$$= (-1)^{t-s+1}E(x_0, \ldots, x_{s-2})E(x_{s+2}, \ldots, x_n);$$

vi) for $m \geq 0$,

$$E(x_0, \ldots, x_m, x_{m+1}, \ldots, x_0) = E^2(x_0, \ldots, x_m) + E^2(x_0, \ldots, x_{m-1});$$

vii) for $m \geq 0$,

$$E(x_0, \ldots, x_m, x_{m+1}, x_{m+2}, \ldots, x_0)$$

$$= E(x_0, \ldots, x_m)\{E(x_0, \ldots, x_{m-1}) + E(x_0, \ldots, x_{m+1})\}.$$

2. i) Putting $E_0 = 1$ we find

$$E_0 = E_1 = 1, \quad E_{n+2} = E_{n+1} + E_n \quad \text{for } n \geq 0;$$

ii) $E_n = u_n$, where $u_n$ is the $n+1^{st}$ Fibonacci number;

iii) $u_n = \frac{1}{\sqrt{5}} \left\{\left(\frac{1 + \sqrt{5}}{2}\right)^{n+1} - \left(\frac{1 - \sqrt{5}}{2}\right)^{n+1}\right\}$

$$= \frac{1}{2^n} \left\{\binom{n+1}{1} + 5\binom{n+1}{3} + 5^2\binom{n+1}{5} + \cdots\right\};$$

iv) a) $u_{n-1}u_{n+1} - u_n^2 = (-1)^{n-1};$

b) $u_n u_{n+1} - u_{n-1} u_{n+2} = (-1)^n;$

c) $u_{n+1} u_{t-s+1} - u_{t+1} u_{n-s+1} = (-1)^{t-s+1} u_{s-1} u_{n-t-1},$

for $0 < s < t < n$;

da) $u_m^2 + u_{m+1}^2 = u_{2m+2}$ for $m \geq 0$;
e) \( u_{m+1}(u_m + u_{m+2}) = u_{2m+3} \) for \( m \geq 0 \);

f) \( u_{n-3} u_{n-1} + u_{n-2} (3u_{n-1} + u_{n-2}) = u_n^2 \);

g) \( u_{n-3}^2 + u_{n-2} (3u_{n-3} + u_{n-4}) = u_{n-1}^2 \);

v) Define the sequence \( a_0, a_1, a_2, \cdots \) by:

\[
a_0 = a, \quad a_1 = b, \quad a_{n+2} = a_n + a_{n+1} \quad \text{for} \quad n \geq 2.
\]

Then \( a_n = u_{n-2}a + u_{n-1}b \) for \( n \geq 2 \).

Given an arbitrary infinite sequence \( a_0, a_1, a_2, \cdots \) of real numbers such that \( a_j \neq 0 \) for \( j \geq 1 \), we define two new infinite sequences \( p_2, p_1, p_0, p_1, \cdots \) or \( q_2, q_1, q_0, q_1, \cdots \) as follows:

\[
p_2 = 0, \quad p_3 = 1, \quad p_m = E(a_0, \cdots, a_m) \quad \text{for} \quad m \geq 0;
\]

\[
q_2 = 1, \quad q_1 = 0, \quad q_0 = 1, \quad q_m = E(a_1, \cdots, a_m) \quad \text{for} \quad m \geq 1.
\]

Noting that \( p_m \) and \( q_m \) for \( m \leq n \) depend only on the first \( n+1 \) terms of the \( a_j \) sequence we see that \( a_0, \cdots, a_n \) determine \( p_2, \cdots, p_n \) and \( q_2, \cdots, q_n \).
We write \([a_0, \cdots, a_n]\) for the (finite) continued fraction
\[
a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cdots + \frac{1}{a_n}}}}
\]
and write \([a_0, a_1, a_2, \cdots]\) for the infinite continued fraction
\[
a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \cdots}}}
\]

It should be noted that while it is clear that a finite continued fraction always denotes a real number in an obvious way it is not at all clear that an infinite continued fraction denotes a real number in any reasonable way. In certain cases we will find that \(\lim_{n \to \infty}[a_0, \cdots, a_n]\) exists and, in those cases, we shall denote the limit by \([a_0, a_1, a_2, \cdots]\) and call this fraction convergent.
When an infinite continued fraction does not converge we call it divergent. For each finite or infinite sequence of \(a_j\) the quantities \(\frac{p_m}{q_m}\) are called convergents to the corresponding finite or infinite continued fraction. The reason for this terminology will become clear in problem \(\#3\) below. Thus if \(\alpha = [a_0, \ldots, a_n]\) or \(\alpha = \lim_{n \to \infty} [a_0, a_1, a_2, \ldots]\), it being assumed in the second case that the limit exists, we call the \(\frac{p_m}{q_m}\) convergents to \(\alpha\). The \(a_j\) themselves are often referred to as the partial quotients of the continued fraction. The continued fractions introduced thus far are often referred to as simple (or regular) continued fractions. Until we generalize the notion every reference to a continued fraction should be read as a reference to a simple continued fraction. In the following, unless stated to the contrary, all \(a_j\), \(j \geq 1\), are to be positive.
3. In this problem in every context in which \( \alpha \) and \( p_j \) or \( q_j \) occur together it is to be presumed that \( \frac{p_j}{q_j} \) is an existent convergent to \( \alpha \).

i-a) \[ [a_0, \ldots, a_n] = \frac{p_n}{q_n} \text{ for } n \geq 0; \]

b) \[ [a_n, \ldots, a_1] = \frac{q_n}{q_{n-1}} \text{ for } n \geq 1; \]

ii) \[ p_k = a_k p_{k-1} + p_{k-2} \quad \text{for } k \geq 0; \]
\[ q_k = a_k q_{k-1} + q_{k-2} \]

iii) \[ [a_0, \ldots, a_{n-1}, a_n + \frac{1}{b}] = \frac{b p_n + p_{n-1}}{b q_n + q_{n-1}}; \]

iv-a) for \( n \geq 0 \), \( p_n q_{n-1} - p_{n-1} q_n = (-1)^{n-1} \)
and \[ \left| \frac{p_n}{q_n} - \frac{p_{n-1}}{q_{n-1}} \right| = \frac{1}{q_n q_{n-1}}; \]

b) for \( n \geq 0 \), \( p_n q_{n-2} - p_{n-2} q_n = (-1)^n a_n \)
and \[ \left| \frac{p_n}{q_n} - \frac{p_{n-2}}{q_{n-2}} \right| = \frac{1}{q_n q_{n-2}}; \]

v) \[ \frac{p_0}{q_0} < \frac{p_2}{q_2} < \frac{p_4}{q_4} < \ldots < \frac{p_{2m}}{q_{2m}} < \ldots < \alpha < \ldots \]
\[ < \frac{p_{2n+1}}{q_{2n+1}} < \ldots < \frac{p_{2}}{q_{2}} < \frac{p_{3}}{q_{3}} < \frac{p_{1}}{q_{1}}; \]

vi) for integral \( a_j \), the sequence \( \frac{p_{n-1}}{q_{n-1}}, \frac{p_{n-1} + p_n}{q_{n-1} + q_n}, \frac{p_{n-1} + 2p_n}{q_{n-1} + 2q_n}, \ldots, \frac{p_{n-1} + a_{n+1} p_n}{q_{n-1} + a_{n+1} q_n} \) (for \( n \geq 1 \)), \( \alpha \), \( \frac{p_{n+1} + p_n}{q_{n+1} + q_n}, \frac{p_n}{q_n} \)
is monotone and, therefore, \( a_{n+1} \) is the largest positive integer \( t \) for which \( \frac{p_n}{q_{n-1}} \) and \( \frac{p_{n-1} + tp_n}{q_{n-1} + tq_n} \)
are on the same side of \( \alpha \);
\[ \frac{1}{q_n(q_n + q_{n+1})} < \left| \alpha - \frac{p_n}{q_n} \right| < \frac{1}{q_n q_{n+1}} ; \]

\( n \geq 1 \)

\[ \frac{q_n \alpha - p_n}{q_n} < \left| \alpha - \frac{p_{n-1}}{q_{n-1}} \right| ; \]

\( n \geq 1 \)

\[ \frac{p_{2n}}{q_{2n}} \text{ and } \frac{p_{2n+1}}{q_{2n+1}} \text{ exist but are equal if and only if } q_n q_{n+1} \to \infty \text{ as } n \to \infty ; \]

\[ \lim_{n \to \infty} [a_0, \ldots, a_n] \text{ exists if and only if } q_n q_{n+1} \to \infty \text{ as } n \to \infty ; \]

\[ \frac{p_{n}}{q_n} = a_0 + \frac{1}{q_0 q_1} - \frac{1}{q_1 q_2} + \frac{1}{q_2 q_3} - \cdots + \frac{(-1)^{n-1}}{q_{n-1} q_n}, \]

for \( n \geq 1 \)

\[ \frac{q_n}{q_0 q_1} \]

\[ \frac{1}{q_0 q_1 q_2} \]

\[ \frac{1}{q_0 q_1 q_2 q_3} \]

\[ \frac{1}{q_0 q_1 q_2 q_3 q_4} \]

\[ \cdots \]

\[ \frac{(-1)^{n-1}}{q_{n-1} q_n}, \]

if all \( a_j \) are integers and \( a_j > 0 \) for \( j \geq 1 \) then:

a) \( p_j \) and \( q_j \) are relatively prime integers;

b) \( |p_n| \) and \( q_n \) tend to infinity with \( n \);

c) \( q_n \geq 2^{n-1} \) for \( n \geq 2 \);

d) \( \lim_{n \to \infty} [a_0, \ldots, a_n] \) exists;

\[ \frac{p_{n}}{q_n} = a_0 + \frac{1}{q_0 q_1} - \frac{1}{q_1 q_2} + \frac{1}{q_2 q_3} - \cdots + \frac{(-1)^{n-1}}{q_{n-1} q_n}, \]

if in the following all \( a_j, b_j, \) and \( c_j \) are integers and, for \( j \geq 1 \), are positive integers:

a) If \( a_j = b_j \), for \( 0 \leq j \leq n \), \( a_n < b_n \), and \( \alpha = [a_0, a_1, \ldots] \), \( \beta = [b_0, b_1, \ldots] \) then \( \alpha < \beta \) when \( n \) is even and \( \alpha > \beta \) when \( n \) is odd.
6) If \( c_j \leq a_j \leq b_j \) for \( j \geq 0 \) then, for \( \alpha = [a_0, a_1, \ldots] \),
\([c_0, b_1, c_2, b_3, c_4, b_5, \ldots] \leq \alpha \leq [b_0, c_1, b_2, c_3, b_4, c_5, \ldots] \);

b) If \( \alpha = [a_0, a_1, \ldots] \), where every \( a_j \) is 1 or 2,
then \( \frac{1+\sqrt{3}}{2} \leq \alpha \leq 1 + \sqrt{3} \).

4. If \( \alpha \) is a rational real number the Euclidean algorithm may be used to compute integers
\( n, a_0, \ldots, a_n \) with \( a_j \geq 0 \), \( j \geq 1 \), for which
\( \alpha = [a_0, \ldots, a_n, 1] = [a_0, \ldots, a_{n-1}, a_n + 1] \). Further, no continued fraction with integral \( a_j \) other
than these two is equal to \( \alpha \).

5. If \( \alpha \) is an arbitrary irrational real number
there exist integers \( a_0, a_1, \ldots \) with \( a_j > 0 \), \( j \geq 1 \),
for which \( \alpha = \lim_{n \to \infty} [a_0, a_1, \ldots, a_n] \).

Further, this sequence is unique.
Remark. Continued fraction expansions of the form \([a_0, a_1, a_2, \ldots]\) (finite or infinite) in which all \(a_j\) are integers and all \(a_j, j \geq 1\), are positive integers are of particular interest. In the following, whenever one refers to the continued fraction expansion of a real number it is that simple continued fraction expansion in which all \(a_j\) are integers and all \(a_j, j \geq 1\), are positive integers. We shall use the abbreviation \(SCF\) for "simple continued fraction".

6. i) Using the recurrence relations in \#3 (ii) devise a simple scheme for the rapid computation of the convergents of a continued fraction.

   ii) Use the scheme of (i) to compute all the convergents to \([2, 2, 1, 3, 1, 1, 4, 3]\). (Note that the last convergent equals this continued fraction.)
iii) Use the Euclidean algorithm to find the scf expansions of $\frac{2227}{991}$ and $\frac{34453}{10349}$.

iv) Reduce the fractions in (iii) to lowest terms by using the results of (iii'), (i) and $3(x^2-a)$.

v) Compute $a_j$, $0 \leq j \leq 5$, for the scf expansion of $\pi$ and find the 1st five convergents $\frac{p_j}{q_j}$, $0 \leq j \leq 4$. Then using $\frac{p_4}{q_4} < \pi < \frac{p_3}{q_3}$, show $|\pi - \frac{p_3}{q_3}| < 3 \cdot 10^{-7}$.

vi) Using the results of (v) for $\frac{p_0}{q_0}, \frac{p_1}{q_1}$ compute $\frac{p_2}{q_2}$ by making use of $\#3$ (vi).

vii) Find the scf expansion of the Golden mean $\frac{1+\sqrt{5}}{2}$.

viii) Compute $\alpha$ in more familiar terms if $\alpha = [a, a, 2a, a, 2a, \ldots] = [a, \overline{a, 2a}]$, $a > 0$.

ix) For a a positive integer, expand $\alpha = \sqrt{a^2-2}$ in a simple continued fraction; use the result to compute the scf expansion of $\sqrt{23}$.

x) $[\underbrace{2, 1, \ldots, 1}, \underbrace{3, 1, \ldots, 1}] = \left(\frac{u_n}{u_{n-i}}\right)^2$. 

xi) $[\underbrace{2, 1, \ldots, 1}, \underbrace{3, 1, \ldots, 1}] = \left(\frac{u_n}{u_{n-i}}\right)^2$. 

$\text{nat}$
7. (Seidel's convergence theorem of 1846)

Let $a_0, a_1, a_2, \ldots$ be an infinite sequence of positive real numbers with the possible exception of $a_0$, which may be negative, and let $\frac{p_i}{q_i}$ be the typical convergent of the infinite continued fraction $[a_0, a_1, a_2, \ldots]$.

i) Suppose $\sum_{n=1}^{\infty} a_n$ converges. Then:

a) if $a_k < 1$ either

$$q_k < \frac{q_{k-1}}{1 - a_k} \text{ or } q_k < \frac{q_{k-2}}{1 - a_k};$$

b) there is a $k_0$ and an $A$ such that

$$q_k < q_s (1 - a_{i_s})^{-1} \cdots (1 - a_{i_r})^{-1} \leq A \left( \frac{\sum_{i=k_0}^{\infty} (1 - a_i)}{i} \right);$$

when $s \leq k_0$ and $k = i_s \cdots i_r > k_0$;

c) $\lim_{n \to \infty} [a_0, \ldots, a_n]$ does not exist.

ii) Suppose $\sum_{n=1}^{\infty} a_n$ diverges. Put $c = \min \{q_0, q_1\}$.

Then:

a) $q_k \geq c$ for $k \geq 0$;

b) $q_k \geq q_{k-2} + ca_k$ for $k \geq 1$;

c) $q_k + q_{k-1} > c \sum_{n=1}^{\infty} a_n$ for $k \geq 3$;

d) $q_k q_{k-1} > \frac{c^2}{2} \sum_{n=1}^{\infty} a_n$ for $k \geq 3$;

e) $\lim_{n \to \infty} [a_0, \ldots, a_n]$ exists.
iii) (Seidel) \( \lim_{n \to \infty} [a_0, \ldots, a_n] \) exists if and only if \( \sum_{n=1}^{\infty} a_n \) diverges;

iv) \( \lim_{n \to \infty} [a_0, \ldots, a_n] \) always exists when the \( a_j \) are all integral, \( a_j > 0 \) for \( j \geq 1 \).

8. (Best approximations of 1st kind)

A fraction which is closer to a real number \( \alpha \) than every other fraction with equal or smaller denominator is called a best approximation of first kind to \( \alpha \). If \( \frac{a}{b} \) is a best approximation of first kind to \( \alpha \) we will write "\( \frac{a}{b} \) is a BA1 to \( \alpha \)."

i) Suppose \( a, b, c, d, x, y \) are positive integers. Then

a) if \( \frac{a}{b} < \frac{x}{y} < \frac{c}{d} \) then \( x \geq \frac{a+c}{bc-ad} \) and \( y \geq \frac{b+d}{bc-ad} \);

b) if \( \frac{a}{b} < \alpha < \frac{c}{d}, \) \( bc-ad=1 \), then at least one of \( \frac{a}{b}, \frac{c}{d} \) is a BA1 to \( \alpha \) and if one of \( \frac{a}{b}, \frac{c}{d} \) is closer to \( \alpha \) that one is a BA1 to \( \alpha \).
ii) Every convergent to $\alpha$ is a BA1 to $\alpha$.

iii) Find 5 BA1's to $\pi$.

iv) The quotients of consecutive Fibonacci numbers are convergents and, therefore, BA1's to the Golden Mean $\frac{1+\sqrt{5}}{2}$.

v) If $\frac{p_{j-1}}{q_{j-1}}$ and $\frac{p_{j+1}}{q_{j+1}}$ are convergents to a real number $\alpha$ and if $\frac{a}{b}$, $(a, b) = 1$, lies between them then $b > q_j$.

9. (Farey fractions) Let $\Phi_n$ be the sequence of all irreducible fractions in $[0, 1]$, whose denominators do not exceed $n$, arranged in order of magnitude. This ordered sequence $\Phi_n$ is called the Farey sequence of order $n$.

i) Write out $\Phi_n$ for $1 \leq n \leq 6$.

ii) The union of the $\Phi_n$, as sets rather than as ordered sets, taken over all positive integers $n$, is precisely the set of rational numbers in $[0, 1]$. 
iii) Let \( \frac{a}{b} \) be in \( \Phi_n \) and suppose \( \frac{a}{b} \neq 1 \). Then:
   a) there is a \( y_0 \) such that
       \[ ay_0 \equiv -1 \pmod{b} \] and \( n - b < y_0 \leq n \);
   b) for \( y_0 \) as in (i) and \( x_0 = \frac{ay_0 + 1}{b} \) the
       fraction next following \( \frac{a}{b} \) in \( \Phi_n \) is \( \frac{x_0}{y_0} \);
   c) it is easy to find the fraction following
       \[ \frac{79}{101} \] in each of \( \Phi_{101} \) and \( \Phi_{200} \);
   d) if \( \frac{a}{b} \) and \( \frac{c}{d} \) are irreducible fractions in
       \( [0,1] \) with \( bc - ad = 1 \) then \( \frac{a}{b} \) and \( \frac{c}{d} \) are
       consecutive elements in \( \Phi_m \), where \( m = \max\{b,d\} \).

iv) If \( \frac{a}{b} < \frac{c}{d} \) and these are neighboring (i.e.
    consecutive) fractions in \( \Phi_n \) then
   a) \( b + d > n \);
   b) \( bc - ad = 1 \);
   c) \( (b,d) = 1 \);
   d) \( b \neq d \) when \( n > 1 \).

v) If \( \alpha \) is between neighboring elements of
    \( \Phi_n \) then at least one of these neighboring ele-
    ments is a BA1 to \( \alpha \).
vi) If \( \frac{a}{b} \), \( \frac{x}{y} \), \( \frac{c}{d} \) are consecutive elements in \( \mathfrak{F}_n \) then:

a) \( bc - ad = (a+c, b+d) \);

b) \( \frac{x}{y} = \frac{\frac{a+c}{b+d}} \);

(The fraction \( \frac{a+c}{b+d} \) appearing in (b) is called the Farey mediant of the fractions \( \frac{a}{b} \) and \( \frac{c}{d} \).

It will be noted that the Farey mediant of two fractions always lies between them.)

vii) All fractions in \( \mathfrak{F}_{n+1} \setminus \mathfrak{F}_n \) are Farey mediants of fractions in \( \mathfrak{F}_n \).

viii) Write out \( \mathfrak{F}_7 \) using (i) \( \mathfrak{F}_7 \).

ix) Let \( \frac{a}{b} \) and \( \frac{c}{d} \) be neighboring fractions in \( \mathfrak{F}_n \) and suppose \( \frac{a}{b} < \alpha < \frac{c}{d} \). Then:

a) If an element of \( \mathfrak{F}_{n+1} \setminus \mathfrak{F}_n \) is a BAI to \( \alpha \) then that element is equal to \( \frac{a+c}{b+d} \);

b) If \( \frac{a+c}{b+d} \) is in \( \mathfrak{F}_{n+1} \setminus \mathfrak{F}_n \) it is a BAI to \( \alpha \) if and only if it is closer to \( \alpha \) than each of \( \frac{a}{b} \) and \( \frac{c}{d} \).

x) Find all the BAI's to \( \pi \) (approximately equal to 3.14159) with denominators not exceeding 125.
10. i) Let \( \alpha \) lie between neighboring fractions \( \frac{a}{b} \) and \( \frac{c}{d} \) in \( \Phi_n \), \( n > 1 \). Then at least one of the following inequalities is true:

\[
|\alpha - \frac{a}{b}| < \frac{1}{2b^2}, \quad |\alpha - \frac{c}{d}| < \frac{1}{2d^2}.
\]

ii) If \( \alpha \) is a real number and \( m \) is a positive integer then there are relatively prime integers \( s \) and \( t \) such that \( |\alpha - \frac{s}{t}| \leq \frac{1}{t(m+1)}, 0 < t \leq m \).

11. (H.J.S. Smith proof of Fermat's 2 square theorem)

i) With the sole exception of 1, every rational number has a simple continued fraction expansion with last partial quotient > 1;

ii) Let \( p \) be an odd prime and let \( 1 \leq t \leq s \), where \( s = \left\lfloor \frac{p}{2} \right\rfloor \). Then there are positive integers \( a_0, \cdots, a_n \) such that \( a_0 > 1 \), \( a_n > 1 \) and

\[
\frac{p}{t} = \left[ a_0, \cdots, a_n \right] = \frac{E(a_0, \cdots, a_n)}{E(a_1, \cdots, a_n)};
\]
iii) Let \( p \) and \( s \) be as in (ii). Then there are exactly \( s \) finite sequences \( a_0, \ldots, a_n \) with \( a_0 > 1, a_n > 1 \) and \( p = E(a_0, \ldots, a_n) \). Further, \( a_n, \ldots, a_0 \) is one of these sequences when \( a_0, \ldots, a_n \) is;

iv) When \( p \equiv 1 \pmod{4} \) then \( s \) is even and, since \( p = E(p) \), there exist \( a_0, \ldots, a_n, a_0 > 1, a_n > 1 \) such that \( p = E(a_0, \ldots, a_n) \) and \( a_j = a_{n-j} \) for \( 0 \leq j \leq n \); i.e. \( a_0, \ldots, a_n \) is palindromic;

v) \( p = E(a_0, \ldots, a_m, a_{m+1}, a_m, \ldots, a_0) \) in (iv) is impossible and, therefore, \( p = a^2 + b^2 \) for suitable \( a \) and \( b \), when \( p \equiv 1 \pmod{4} \);

vi) The above proof is constructive. Use it to represent 13 as a sum of 2 squares.

12. i) If in (ii) we take \( \alpha = \frac{a}{b} \), \( (a, b) = 1 \), \( m = \lceil \sqrt{b} \rceil \) then the \( s \) and \( t \) of that result satisfy:

a) \( 0 < (at - bs)^2 + t^2 < 2b \);

b) \( (at - bs, t) = 1 \) when \( b \) divides \( a^2 + 1 \);

c) \( 0 < t \leq \sqrt{b} \).
ii) Every divisor of a number of the form $a^2 + 1$ is a sum of relatively prime squares;

iii) (Fermat’s 2 square theorem again)

Wilson’s theorem guarantees that every prime of the form $4k+1$ divides a number of the form $a^2 + 1$ and, therefore, by (ii) must be a sum of relatively prime squares;

iv) If $(a, c) = 1$ and $b | a^2 + c^2$ then there is an integer $u$ such that $b$ divides $(au)^2 + 1$;

v) Every divisor of a sum of relatively prime squares is itself such a sum and if it is respectively odd, even must then be of the form $4k+1, 4k+2$.

13. (Best approximations of 2\textsuperscript{nd} kind)

If $a$ and $b$ are relatively prime positive integers and $|a^2 - a| < |a^2 - c|$ for all pairs $c,d$ of relatively prime positive integers satisfying $d \leq b$ and $\frac{c}{d} \neq \frac{a}{b}$ then $\frac{a}{b}$ is called a best
approximation of the 2nd kind to \( \alpha \). We abbreviate this last phrase by writing "\( \frac{a}{b} \) is a BA2 to \( \alpha \)."

i) Every BA2 to \( \alpha \) is a BA1 to \( \alpha \);

ii) The converse of (i) is false;

iii) Let \( \frac{a}{b} \) be a BA2 to an irrational number \( \alpha \). Clearly either \( \frac{a}{b} \) is a convergent to \( \alpha \) or it lies in one of the open intervals (see diagram) determined by the convergents to \( \alpha \).

\[
\begin{array}{cccccccc}
P_0 & P_2 & P_4 & \ldots & \alpha & \ldots & P_5 & P_3 & P_1 \\
q_0 & q_2 & q_4 & \ldots & q_5 & q_3 & q_1 \\
\end{array}
\]

Further,

a) \( \frac{a}{b} < \frac{P_0}{q_0} \) is not possible;

b) \( \frac{a}{b} > \frac{P_1}{q_1} \) is not possible;

c) if \( \frac{a}{b} \) is strictly between \( \frac{P_{k-1}}{q_{k-1}} \) and \( \frac{P_{k+1}}{q_{k+1}} \),

then \( b > q_k \), \( |\alpha - \frac{a}{b}| \geq \frac{1}{b q_k} \) and \( \frac{P_k}{q_k} \), \( |\alpha - \frac{P_k}{q_k}| < \frac{1}{q_k q_{k+1}} \);

da) the supposition in (c) is unrealizable;

e) every BA2 to \( \alpha \) is a convergent to \( \alpha \).
w) Let the \( \frac{p_i}{q_j} \) below be the convergents to the irrational number \( \alpha \). Then:

a) \( |\alpha q_n - p_n| < |\alpha q_{n-1} - p_{n-1}| \);
b) \( q_n |\alpha q_{n-1} - p_{n-1}| + q_{n-1} |\alpha q_n - p_n| = 1 \);
c) when \( \frac{a}{b} \neq \frac{p_{n-1}}{q_{n-1}} \) then
\[ b |\alpha q_{n-1} - p_{n-1}| + q_{n-1} |\alpha b - a| \geq 1 \];
d) when \( 1 \leq b \leq q_n \) then
\[ b |\alpha q_{n-1} - p_{n-1}| + q_{n-1} |\alpha q_n - p_n| \leq 1 \];
e) for all positive integers \( a, b \) with \( 1 \leq b \leq q_n \), \( |\alpha q_n - p_n| \leq |\alpha b - a| \);
f) every convergent to \( \alpha \) is a \( \text{BA2} \) to \( \alpha \);

( the simplicity of this argument is due to Drobot [1963]. )

v) A fraction is a \( \text{BA2} \) to an irrational number \( \alpha \) if and only if it is a convergent to \( \alpha \).

14. At least one, say \( \frac{a}{b} \), of each pair of consecutive convergents to \( \alpha \) satisfies
\[ |\alpha - \frac{a}{b}| < \frac{1}{2b^2} \].
15. i) Let $\alpha$ be a real number and $\frac{a}{b}$ be a reduced fraction satisfying $|\alpha - \frac{a}{b}| < \frac{1}{2b^2}$. Further, let $[a_o, \ldots, a_s]$ be that scf expansion of $\frac{a}{b}$ for which $s$ is even, odd in the respective cases $\frac{a}{b} < \alpha, \frac{a}{b} > \alpha$. When $\frac{p_{s-1}}{q_{s-1}}, \frac{p_s}{q_s}$ are the last two convergents to $\frac{a}{b}$ and $\alpha' = \frac{\alpha q_s - p_s}{p_{s-1} - \alpha q_{s-1}}$, we have $\alpha' \geq 0$ and $\alpha = [a_o, \ldots, a_s + \alpha']$;

ii) If $\frac{a}{b}, \alpha$ and $\alpha'$ are as in (i) then $\frac{1}{\alpha'} + \frac{q_{s-1}}{q_s} > 2$ so $0 < \alpha' < 1$ and we conclude $a_o, \ldots, a_s$ are the first $s+1$ partial quotients in the scf expansion of $\alpha$;

iii) (Dirichlet) If $\frac{a}{b}$ is a fraction such that $|\alpha - \frac{a}{b}| < \frac{1}{2b^2}$ then $\frac{a}{b}$ is a convergent to $\alpha$;

iv) Every rational number is a convergent for uncountably many real numbers;

v) a positive integer $n$ is a Fibonacci number if and only if $5n^2 + 4$ or $5n^2 - 4$ is a square.
16. (Hurwitz' theorem is a result of Markov)

In the following all $\frac{p_j}{q_j}$ are convergents to $\alpha$. Also, we refer to the inequality

$|\alpha - \frac{p_n}{q_n}| \geq \frac{1}{\sqrt{5} q_n^2}$ as (*). Finally, we call two real numbers equivalent if their scf expansions have the same tails (i.e. if $\alpha = [a_0, a_1, \ldots]$ and $\beta = [b_0, b_1, \ldots]$ then $\alpha$ and $\beta$ are equivalent if for some $s$ and $t$ it is true that $a_{s+t} = b_{s+t}$ for $j \geq 0$).

i) a) If (*) is true for $n = s - 1$ and $n = s$ then

$\frac{1}{\sqrt{5}} \left( \frac{1}{q_{s-1}} + \frac{1}{q_s} \right) \leq \frac{1}{q_{s-1} q_s};$

b) under the conditions in (a) each of

$\frac{q_{s-1}}{q_s}$ and $\frac{q_s}{q_{s-1}}$ is in the open interval

$(\frac{\sqrt{5} - 1}{2}, \frac{\sqrt{5} + 1}{2});$

c) if (*) is true for $n = s - 1, n = s$ and $n = s + 1$ then $a_{s+1} = \frac{q_{s+1}}{q_s} - \frac{q_{s-1}}{q_s} < 1;$

d) at least one of any three convergents to $\alpha$ satisfies $|\alpha - \frac{p_n}{q_n}| < \frac{1}{\sqrt{5} q_n^2};$
e) (Hurwitz) if \( \alpha \) is irrational there are infinitely many irreducible rational numbers \( \frac{a}{b} \) such that \( |\alpha - \frac{a}{b}| < \frac{1}{\sqrt{5} b^2} \).

ii) Hurwitz' theorem is false if we replace \( \sqrt{5} \) by any larger number. In fact, if \( 0 < \beta < 1 \) then there are only finitely many irreducible rational numbers \( \frac{a}{b} \) such that

\[
|\frac{1+\sqrt{5}}{2} - \frac{a}{b}| < \frac{\beta}{\sqrt{5} b^2}.
\]

iii-a) If \( |\alpha - \frac{p_n}{q_n}| \geq \frac{1}{q_n^2 \sqrt{m^2 + 4}} \) for each of \( n = s-1, n = s \) and \( n = s+1 \) then \( a_{s+1} < m \);

b) if \( \alpha \) is irrational either there are infinitely many irreducible fractions \( \frac{a}{b} \) satisfying \( |\alpha - \frac{a}{b}| < \frac{1}{b^2 \sqrt{m^2 + 4}} \) or there is an \( s_0 \) such that \( a_s < m \) for all \( s > s_0 \);

c) (Markov) if \( \alpha \) is irrational and not equivalent to \( \frac{1+\sqrt{5}}{2} \) then there are infinitely many irreducible rational numbers \( \frac{a}{b} \) such that \( |\alpha - \frac{a}{b}| < \frac{1}{2 \sqrt{2} b^2} \) (i.e. if one removes all real numbers
equivalent to \( \frac{1+\sqrt{5}}{2} \) then the Hurwitz' theorem is no longer best possible and, in fact, the \( \sqrt{5} \) of that theorem may be replaced by \( 2\sqrt{2} \).

\( iv) \) Let \([a_0,a_1,\ldots]\) be the scf expansion of an irrational number \( \alpha \) and suppose the \( \frac{p_n}{q_n} \) are the convergents to \( \alpha \). Define

\[ \nu(\alpha) = \liminf q_n | q_n \alpha - p_n |. \]

Then:

a) \( \#3 (iv) \) guarantees \( \nu(\alpha) \leq 1 \);

b) Hurwitz' theorem guarantees \( \nu(\alpha) \leq \frac{1}{\sqrt{5}} \);

c) for \( \alpha \) not equivalent to \( \frac{1+\sqrt{5}}{2} \), (iii-c) guarantees \( \nu(\alpha) \leq \frac{1}{\sqrt{5}} \);

da) (iii-b) guarantees that either

\[ \nu(\alpha) \leq \frac{1}{\sqrt{m^2+4}} \]

or for all \( a_s \) with \( s \) sufficiently large we have \( a_s < m \);

e) if infinitely many \( a_j \) are \( \geq 3 \) then

\[ \nu(\alpha) \leq \frac{1}{\sqrt{13}} \]
v) With the same notation as in (\(\nu\)) and putting \(\alpha_n = [a_{n+1}, a_{n+2}, \ldots] \) we have:

\[ \alpha = [a_0, \ldots, a_{n-1}, a_n + \frac{1}{a_n}] = \frac{\alpha_n p_n + p_{n-1}}{\alpha_n q_n + q_{n-1}} \]

and, therefore, \(q_n | q_n \alpha - p_n| = \frac{1}{\alpha_n + \frac{1}{q_{n-1}}} \)

b) If \(a_j \leq 2\) for all but a finite number of \(j\) then, for \(n\) sufficiently large,

\[ \frac{1}{q_n |q_n \alpha - p_n|} = [a_{n+1}, a_{n+2}, \ldots] + [0, a_n, a_{n-1}, \ldots, a_1] \]

\[ \leq [2, 1, 2, 1, \ldots] + [0, 1, 2, 1, 2, \ldots] \]

\[ \leq 1 + \sqrt{3} + \frac{2}{1 + \sqrt{3}} = 2 \sqrt{3} \]

and, therefore, \(\nu(\alpha) \geq \frac{1}{\sqrt{12}} \)

c) \(\nu(\alpha)\) cannot lie between \(\frac{1}{\sqrt{13}}\) and \(\frac{1}{\sqrt{12}}\).

Remark. The results in problem \#16 are by no means exhaustive of those known. For further details one may consult Cassels [1957] chpt II. The extreme simplicity of the above arguments is due to Forder [1963] and Wright [1964]. For results like those in (\(\nu - c\)) and further references see Cusick [1974].
17. (Periodic scf's)

When \( a_j = a_{j+t} \) for \( j > s \) we say that
\[ [a_o, a_1, \cdots] \]
is periodic with period \( a_s, \cdots a_{s+t} \) and write
\[ [a_o, a_1, \cdots] = [a_o, \cdots, a_s, \overline{a_{s+1}, \cdots a_{s+t}}] \].

For purely periodic scf's such as \([a_o, \cdots, a_{t-1}]\)
we conventionally write the above with \( s = -1 \).

i) If \( \alpha \) is a periodic scf then \( \alpha \) is a quadratic irrational;

ii) let \( \alpha \) be a quadratic irrational which is a zero of the integral polynomial
\[ f(x) = A x^2 + B x + C \],
where the integers \( A, B, C \) have no common factor \( > 1 \); further, put
\( \alpha = [a_o, a_1, \cdots] \) and \( \alpha_n = [a_{n+1}, a_{n+2}, \cdots] \).
Then

a) \( \alpha_n \) is a quadratic irrational for all \( n \geq 0 \);

b) if \( \alpha_n \) is a zero of the integral polynomial
\( A_n x^2 + B_n x + C_n \), \( (A_n, B_n, C_n) = 1 \), then
\[ B_n^2 - 4A_n C_n = B^2 - 4AC \];
i.e. all \( \alpha_n \) have the same discriminant;
c) in (6), \( A_n = q_n^2 \int \left( \frac{p_n}{q_n} \right) \), \( C_n = q_{n-1}^2 \int \left( \frac{p_{n-1}}{q_{n-1}} \right) \), and this implies that \( A_n C_n < 0 \);  

d) there are only finitely many distinct triples \( A_n, B_n, C_n \);  

e) there are positive integers \( k \) and \( n \) such that \( \alpha_{k+n} = \alpha_k \), and, therefore, \( \alpha \) is periodic.

iii) For \( P, Q, D \) integers with \( D \) a positive non-square, the number \( \alpha = \frac{P + \sqrt{D}}{Q} \) is a quadratic irrational. The conjugate \( \alpha' \) of \( \alpha \) is given by \( \alpha' = \frac{P - \sqrt{D}}{Q} \). A quadratic irrational \( \alpha \), \( \alpha > 1 \), satisfying \(-1 < \alpha' < 0\) is called reduced. Thus \( \frac{P + \sqrt{D}}{Q} \) is reduced when 

\[-1 < \frac{P - \sqrt{D}}{Q} < 0 < \frac{P + \sqrt{D}}{Q}.\]  
The quantities \( \alpha_n \) are defined as in (ii).

a) If \( \alpha \) has a purely periodic scf expansion then \( \alpha \) is reduced;  

b) if \( \alpha \) is reduced and \( \alpha = a_\alpha + \frac{1}{\alpha_\alpha} \) then \( \alpha_\alpha \) is reduced;
c) If $\alpha$ is reduced so also are all $\alpha_n$;

d) If $\alpha$ is reduced and has a non-purely periodic expansion

$$\alpha = [a_0, \ldots, a_s, \overline{a_{s+1}, \ldots, a_{s+t}}], a_s \neq a_{s+t},$$

then $\alpha_{s-1} - \alpha'_{s+t-1} = a_s - a_{s+t}$ and, therefore,

$$\alpha'_{s-1} - \alpha'_{s+t-1} = a_s - a_{s+t} ;$$

e) Under the hypothesis of (d) the conclusion obtained is impossible. Consequently a reduced quadratic irrational must have a purely periodic scf expansion;

f) Necessary and sufficient conditions that a quadratic irrational $\alpha$ have a purely periodic scf expansion is that it be reduced; i.e. that $\alpha > 1$ and $-1 < \alpha' < 0$.

ii) a) Are the scf expansions of $\frac{1 + \sqrt{13}}{3}$, $\frac{1 - \sqrt{13}}{3}$, $\frac{2 + \sqrt{3}}{4}$ purely periodic?

b) Compute the scf expansions of $\frac{1 + \sqrt{13}}{3}$ and $-\left(\frac{1 - \sqrt{13}}{3}\right)^{-1}$;
c) If \( \alpha \) is reduced then the period of \(-((\alpha'))^{-1}\)
is the reverse of the period of \( \alpha \).

v) Let \( Q, D \) be positive integers with \( D > Q^2 \)
and \( \alpha = \frac{\sqrt{D}}{Q} \) be irrational. Then the scf expansion
of \( \alpha \) has the form \([a_0, a_1, \ldots, a_k, 2a_0]\).

vi) Let \( D \) be a positive integer such that \( \sqrt{D} \)
is irrational. Then, if \( a_0 = [\sqrt{D}] \),
\( a) \frac{1}{\sqrt{D} - a_0} \) is reduced;
\( b) \sqrt{D} + a_0 \) is reduced and its scf expansion
period is the reverse of that of \( \frac{1}{\sqrt{D} - a_0} \);
\( c) \) The scf expansion of \( \sqrt{D} \) is of the form
\( \sqrt{D} = [a_0, a_1, a_2, \ldots, a_k, 2a_0]. \)

vii) Let \( D \) be a positive integer with \( \sqrt{D} \)
irrational. Then we may write
\( \sqrt{D} = [a_0, a_1, \ldots, a_{k-1}, 2a_0] = [a_0, a_1, \ldots], \)
where \( k \) is the length of the minimum period.
Further put, as usual, \( \alpha_m = [a_{m1}, a_{m2}, \ldots] \).

Finally, suppose \( x_o^2 - Dy_o^2 = 1 \) where \( x_o > 0, y_o > 0 \).

Then

a) \( \frac{x_o}{y_o} \) is a convergent to \( \sqrt{D} \), say \( \frac{x_o}{y_o} = \frac{p_s}{q_s} \);

b) with \( s \) as in (a):

A) if \( A_s x^2 + B_s x + C_s = 0 \) is the integral quadratic equation with \( (A_s, B_s, C_s) = 1 \) satisfied by \( \alpha_s \) then

\[
A_s = 1 , \quad B_s^2 = 4 (C_s + D) , \quad C_s = p_{s-1}^2 - Dq_{s-1}^2 ;
\]

B) \( \alpha_s = -\frac{1}{2} B_s + \sqrt{D} \);

c) \( -\frac{1}{2} B_s = a_0 \);

D) \( a_j = a_{j-s+1} \) for \( j \geq 1 \);

E) \( s \equiv -1 \pmod{k} \);

c) all positive integral solutions of \( x^2 - Dy^2 = 1 \) are contained in the sequence

\[
\{(p_{k-1}, q_{k-1}), (p_{2k-1}, q_{2k-1}), (p_{3k-1}, q_{3k-1}), \ldots\} ;
\]

da) \( \sqrt{D} = [a_0, a_1, \ldots, a_{tk-1} + \frac{1}{a_0 + \sqrt{D}}] \), and,

therefore,
\[ p_{t+1} = a_0 q_{t+1} + q_{t+2}, \]
\[ Dq_{t+1} = a_0 p_{t+1} + p_{t+2}, \]
\[ p_{t+1}^2 - Dq_{t+1}^2 = (-1)^{t+1}. \]

c) \( x^2 - Dy^2 = 1 \) has infinitely many positive solutions and the totality of positive solutions consists precisely of the terms in the sequence of (c) with odd subscripts;

f) find the least positive integral solutions to:

A) \( x^2 - 22y^2 = 1 \);

B) \( x^2 - 13y^2 = 1 \);

C) \( x^2 - 33y^2 = 1 \);

g) develop an analogous theory for the equation \( x^2 - Dy^2 = -1 \).

18. Suppose \( a \) and \( b \) are positive relatively prime integers with \( a > b \) and \( \frac{a}{b} = [a_0, \ldots, a_n] \), \( a_n \geq 2 \).

i) \( E_n \leq b \), where \( E_n \) is the number of summands in \( E(x_1, \ldots, x_n) \);
ii) Let \( z = \frac{1 + \sqrt{5}}{2} \) and noting that \( z^2 = 1 + z \) deduce \( z^n < E_{n+1} \);

iii) \( n < \frac{\log b}{\log \frac{1 + \sqrt{5}}{2}} \);

w) If \( 10^{t-1} \leq b < 10^t \) then \( n < 5t \);

v) (Lamé) the number of divisions required to find the gcd of two numbers by means of the Euclidean algorithm never exceeds five times the number of base 10 digits of the smaller of the two numbers;

vi) investigate the best possible nature of Lamé's theorem.

19. (The circle diagram)

Corresponding to each irreducible fraction \( \frac{a}{b} \) in \([0, 1]\) construct the circle, \( C(\frac{a}{b}) \), of radius \( \frac{1}{2b^2} \) and with center at \( (\frac{a}{b}, \frac{1}{2b^2}) \). Then \( C(\frac{a}{b}) \) is a circle lying above and tangent to the x-axis at \( \frac{a}{b} \).
i) \( C(\frac{a}{b}) , C(\frac{c}{d}) \) for \( \frac{a}{b} \neq \frac{c}{d} \) are either disjoint or tangent and are tangent precisely when \( \frac{a}{b} \) and \( \frac{c}{d} \) are neighboring fractions in some \( \mathbb{Q}_n \) (see \#9);

ii) the point of tangency between tangent circles is the rational point \( (\frac{ab+cd}{b^2+d^2}, \frac{1}{b^2+d^2}) \);

iii) a vertical line intersecting the \( x \)-axis at \( \alpha \), \( 0 \leq \alpha \leq 1 \), cuts infinitely many of the circles if and only if \( \alpha \) is irrational;

iv) suppose the vertical line cutting the \( x \)-axis at the irrational \( \alpha \) cuts the curved-linear triangle formed by pairwise tangent circles above \( \frac{a}{b}, \frac{c}{d}, \frac{e}{f} \) where \( 0 < \frac{a}{b} < \frac{c}{d} < \frac{e}{f} < 1 \). Then

a) \( \frac{a}{b} < \alpha < \frac{e}{f} \);
b) \( e = a+c, f = b+d \);
c) either \( 0 < d < b < f \) or \( 0 < b < d < f \);
d) If \( 0 < b < d < f \) the vertical line above \( 1 - \alpha \) cuts a similar triangle with circles corresponding to some fractions \( \frac{a'}{b'}, \frac{c'}{d'}, \frac{f'}{g'} \) with \( \frac{a'}{b'} < \frac{f'}{g'} < \frac{c'}{d'} \) and \( 0 < d' < b' < f' \);

e) Rational approximations to \( \alpha \) lead to equally good rational approximations to \( 1 - \alpha \) and vice versa.

20. Let \( \frac{a}{b} < \frac{c}{d} \), \( 0 < d < b < f \), and suppose the circles above these fractions (see \#19) are pairwise tangent with \( A, B, C \) the \( x \)-coordinates of the respective points of tangency of the pairs
\[
\frac{a}{b}, \frac{c}{d} ; \frac{a}{b}, \frac{c}{f} ; \frac{c}{f}, \frac{c}{d}.
\]
Further, suppose \( \alpha \) is irrational and that the vertical line above \( \alpha \) cuts the curvilinear triangle formed by the three circles.
i) Diagrams show clearly the possibility of \( A \leq B < C \) as well as of \( B \leq A < C \);

ii) \( A < C \) and \( B < C \);

iii) a) \( A < B \) when \( \frac{\varepsilon}{d} > \frac{1 + \sqrt{5}}{2} \);

   b) \( A > B \) when \( \frac{\varepsilon}{d} < \frac{1 + \sqrt{5}}{2} \);

iv) a) \( A < B \) implies \( |\alpha - \frac{c}{d}| < \frac{1}{\sqrt{5}d^2} \);

   b) \( A > B \) implies \( |\alpha - \frac{c}{d}| < \frac{1}{\sqrt{5}d^2} \);

v) (Hurwitz) for \( \alpha \) irrational there are infinitely many irreducible fractions such that \( |\alpha - \frac{a}{b}| < \frac{1}{\sqrt{5}b^2} \).

Remarks. The geometrical proof of Hurwitz' theorem which is presented in \#19, 20 goes back to Ford [1917]. See also Rademacher [1964] for an exposition of the proof. An interesting discussion of these circles, sometimes referred to as Ford circles, will be found in Züllig [1928].
21. (Klein’s geometrical interpretation of continued fractions)

Let $L$ be a line through the origin with irrational slope $\alpha$ and suppose $\alpha = [a_0, a_1, \ldots]$. 

i) Points $(x, y)$ are below (above) $L$ precisely when $y < \alpha x$ ($y > \alpha x$); 

ii) Consider the points $P_n = (q_n, p_n)$, where $\frac{p_n}{q_n}$ is a convergent to $\alpha$, and show the vector from $P_{n-2}$ to $P_n$ is $a_n$ times the vector from $O$ to $P_{n-1}$; 

iii) The triangle $O P_{n-1} P_n$ has area $\frac{1}{2}$ and, therefore, contains no lattice points other than its vertices; 

iv) A thread along $L$ when pulled to the right or left and constrained to stick at lattice points (other than $O$) sticks on the lower side of $L$ precisely on the even convergent points and on the upper side of $L$ precisely on the odd convergent points.
22. (Some expansions due to Euler & Hurwitz)

i) Let \( f_n(x) \) denote the value of \( \sum_{s=0}^{\infty} a_{ns} x^{2s} \), where \( a_{ns} = \frac{(n+s)!}{s!(2n+2s)!} \), when the series converges.

   a) \( f_n(x) \) exists for all \( x \);  
   b) \( f_n(x) - (4n+2)f_{n+1}(x) = 4x^2f_{n+2}(x) \) for \( n \geq 0 \);
   c) \( \frac{f_0(x)}{f_1(x)} = 2x \frac{e^{2x} + 1}{e^{2x} - 1} \);
   d) \( \frac{e^{2x}}{e^{2x} - 1} = \left[ \frac{1}{x}, \frac{3}{x}, \frac{5}{x}, \frac{7}{x}, \cdots \right] \) for \( x \neq 0 \);

ii) Let \( \alpha = [a_0, a_1, \cdots] \), where

\[
\begin{align*}
  a_0 &= 2, \\
  a_{3n} &= a_{3n+1} = 1, \\
  a_{3n-1} &= 2n.
\end{align*}
\]

Thus, \( \alpha = [2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, \cdots] \).

Further, let the convergents of \( \alpha \) be \( \frac{p_j}{q_j} \), \( j \geq 0 \). Then:

a) \[
\begin{align*}
  p_{3n+1} &= (4n+2)p_{3n-2} + p_{3n-5} \quad \text{for } n \geq 2; \\
  q_{3n+1} &= (4n+2)q_{3n-2} + q_{3n-5} \quad \text{for } n \geq 1;
\end{align*}
\]
6) If \( P_n / Q_n \) is the \( n^{th} \) convergent to \( \frac{c + i}{c - 1} \), then \( P_n = \frac{1}{2} (p_{3n+1} + q_{3n+1}) \), \( Q_n = \frac{1}{2} (p_{3n+1} - q_{3n+1}) \); 

\[ \alpha = c . \]

iii) a) \( \frac{c \sqrt{2} + 1}{c \sqrt{2} - 1} = [\sqrt{2}, 3, 5, 7, 9, \cdots] \) ;

b) \( \sqrt{2} \left( \frac{c \sqrt{2} + 1}{c \sqrt{2} - 1} \right) = [2, 3, 10, 7, 18, 11, 26, \cdots] \) is not periodic ;

\( e^{\sqrt{2}} \) is irrational .

(This proof is due to Richard E. Crandall .)

23. (A matricial approach)

I. Let \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) and write \( K_1(A) = \frac{a}{c} \), when \( c \neq 0 \), and \( K_2(A) = \frac{b}{d} \), when \( d \neq 0 \). If

\( K_1(A_1 \cdots A_n) \rightarrow \alpha_1 \) we write \( K_1(A_1 \cdots) = \alpha_1 \).

Similarly for \( K_2(A_1 \cdots) \). If \( K_1(A_1 \cdots) = K_2(A_1 \cdots) = \alpha \) we write \( K(A_1 \cdots) = \alpha \). In the following , \( \alpha = [a_0, a_1, \cdots] \).

i) if the \( \frac{P_j}{Q_j} \) are convergents to \( \alpha \) then

\[
\begin{pmatrix} P_n \\ Q_n \end{pmatrix} = \begin{pmatrix} a_0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a_1 & 1 \\ 1 & 0 \end{pmatrix} \cdots \begin{pmatrix} a_n & 1 \\ 1 & 0 \end{pmatrix} ;
\]
ii) \( [a_0, a_1, \ldots] = K \{ (a_{i+1}) (a_i) \ldots \} ; \)

iii) if \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \), \( K_1(A_1 \ldots) = \alpha \), and \( c\alpha + d \neq 0 \),
then \( K_1(AA_1A_2 \ldots) = \frac{a\alpha + b}{c\alpha + d} ; \)

iv) if \( kA = \begin{pmatrix} ka & kb \\ kc & kd \end{pmatrix} \) for \( k \) a number then
\( K_1(A_1 \ldots) = \alpha \) implies \( K_1((k_1A_1)(k_2A_2) \ldots) = \alpha \),
for \( \{k_k\} \) an arbitrary numerical sequence;

v) if \( K_1(A_1 \ldots) = \alpha \) then
\( K_1((A_1A_2A_3)(A_4A_5A_6) \ldots (A_{3n-2}A_{3n-1}A_{3n}) \ldots) = \alpha ; \)

vi) let \( A_1 \ldots A_n = \begin{pmatrix} p_n & r_n \\ q_n & s_n \end{pmatrix} = P_n \); then
\[ \left| K_1(P_n) - K_2(P_n) \right| = \frac{\begin{vmatrix} r_n & \det A_r \\ q_n & s_n \end{vmatrix}}{r_n \det A_r} ; \]

vii) let \( P_n \) be as in (vi), \( |\det A_r| = 1 \) for all \( r \),
\( K(\lim P_n) = \alpha \), \( B = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \); then
a) \( q_n s_n \rightarrow \infty \) as \( n \rightarrow \infty \);
b) \( a^2 + c^2 \neq 0 \) implies \( K_1(P_nB) \rightarrow \alpha ) \);
c) \( b^2 + d^2 \neq 0 \) implies \( K_2(P_nB) \rightarrow \alpha ) \);
da) \( B \) has no zero column implies
\( K(\lim P_nB) = \alpha ; \)
viii) if all $A_r$ have determinant $\pm 1$, $B$ is non-singular, $K(A_1 \cdots) = \alpha$, and $C_r = B^{-1} A_r B$ for all $r$, then $K(BC_1 C_2 \cdots) = \alpha$;

ix) let $ad - bc = \pm 1$, $0 < d < c$; then for $d \geq 1$,

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} b & a-xb \\ c & xd \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}
\]

for all $x$; for $d = 1$,

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} b & a-bc \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} a-(c-1)b & bc-a \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix};
\]

x) under the conditions of (ix) there is an integer $a_0$ and positive integers $n, a_1, \cdots, a_n$ such that

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a_1 & 1 \\ 0 & 0 \end{pmatrix} \cdots \begin{pmatrix} a_n & 1 \\ 0 & 0 \end{pmatrix};
\]

II. Put $A_m = \begin{pmatrix} (2m-1-x) & 2m-1 \\ 2m-1 & 2m-1-x \end{pmatrix}$ for $m = 1, 2, \cdots$ and suppose $\prod_{m=1}^n A_m = \begin{pmatrix} f_n(x) & g_n(x) \\ h_n(x) & k_n(x) \end{pmatrix}$. Then

i) $h_n(x) = g_n(x)$ and $k_n(x) = f_n(-x)$;

ii) a) $f_n(x) = \sum_{k=0}^n \frac{n(n-k-1)}{(n-k)!k!} x^k$;

b) $g_n(x) = \sum_{k=0}^n \frac{(n-k)(n-k-1)!}{(n-k)!k!} x^k$;

iii) a) $\frac{f_n(x)}{n(n+1)\cdots(2n-1)} \rightarrow e^{x/2}$;

b) $\frac{g_n(x)}{n(n+1)\cdots(2n-1)} \rightarrow e^{x/2}$;

w) $K(A, A_2 \cdots) = e^x$ for all $x$. 

v-a \) \begin{pmatrix} a+1 & a \\ a & a-1 \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a-1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} ;

b) \text{ for } k > 0 ,

\begin{bmatrix} 1, k-1, 1, 1, 3k-1, 1, 1, 5k-1, 1, \ldots \end{bmatrix} = e^{\frac{1}{k}} ;

c) e = \begin{bmatrix} 2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, \ldots \end{bmatrix} ;

(\text{The method of this problem is due to Walters [1968].})

24. I we write \( \frac{b_1}{a_1} - \frac{b_2}{a_2} - \frac{b_3}{a_3} - \cdots \) for the continued fraction \( a_1 - \frac{b_2}{a_2} - \frac{b_3}{a_3} - \cdots \).

Further, let \( c_n = \frac{b_1}{a_1} - \frac{b_2}{a_2} - \frac{b_3}{a_3} - \cdots \frac{b_n}{a_n} \) and define \( b_0 = 1 \)

\( p_{-1} = -1 \) \( p_0 = 0 \) \( p_n = a_n p_{n-1} - b_n p_{n-2} \) for \( n \geq 1 \).

\( q_{-1} = 0 \) \( q_0 = 1 \) \( q_n = a_n q_{n-1} - b_n q_{n-2} \) \( q_n = a_n q_{n-1} - b_n q_{n-2} \).

Finally, in all parts below we assume all \( a_j \) and \( b_j \) positive and \( a_n \geq b_{n+1} \) for \( n \geq 0 \).
\( i) \quad c_n = \frac{p_n}{q_n} \text{ for } n \geq 1; \\
\text{ii) for } n \geq 0 \quad p_n \geq p_{n-1} + b_0 \ldots b_n, \quad q_n \geq q_{n-1} + b_0 \ldots b_n \quad \text{so} \\
\quad p_n = b_0 + b_0 b_1 + \ldots + b_0 \ldots b_n, \quad q_n = b_0 + b_0 b_1 + \ldots + b_0 \ldots b_n \\
\text{and strict inequality holds unless } a_j = b_j + 1 \text{ for } 0 \leq j \leq n, \text{ in which case equality holds;} \\
\text{iii) } p_n q_{n-1} - p_{n-1} q_n = b_0 \ldots b_n \text{ for } n \geq 0 \text{ so} \\
\quad \frac{p_n}{q_n} = \frac{p_{n-1}}{q_{n-1}} + \frac{b_0 \ldots b_n}{q_n q_{n-1}}; \\
\text{iv) } q_n - p_n \geq q_{n-1} - p_{n-1} \geq 1 \text{ for } n \geq 0; \text{ further, for a given } n, \text{ if } a_j = b_j + 1 \text{ for } j \leq n \text{ then} \\
\text{both inequalities are equalities, otherwise, at least one of the inequalities is strict;} \\
\text{v) } \lim_{n \to \infty} \frac{p_n}{q_n} \text{ exists and is always } \leq 1; \text{ if } a_n = b_n + 1 \text{ for some } n \text{ then } \lim_{n \to \infty} \frac{p_n}{q_n} < 1; \\
\text{vi) when } a_n = b_n + 1 \text{ for all } n \text{ then} \\
\quad b_0 + b_0 b_1 + \ldots + b_0 \ldots b_n \text{ diverges} \\
\quad \text{implies } \frac{p_n}{q_n} \to 1; \\
\alpha = b_0 + b_0 b_1 + \ldots + b_0 \ldots b_n + \ldots \text{ implies} \\
\quad \frac{p_n}{q_n} \to 1 - \frac{1}{\alpha}; \)
II. Let all \( a_i, b_i \) be positive integers and suppose \( a_n \geq b_{n+1} \) for all \( n \geq 1 \), with strict inequality holding infinitely often.

Write \( \alpha_n = \frac{b_n}{a_n} - \frac{b_{n+1}}{a_{n+1}} \ldots \) and prove:

i) \( 0 < \alpha_n < 1 \) for all \( n \geq 1 \);

ii) if any \( \alpha_j \) is rational so also are all others;

iii) if \( r \) and \( s \) are positive integers and \( \alpha_j = \frac{r}{s} \) then there is a positive integer \( t < r \) such that \( \alpha_{j+t} = \frac{t}{r} \);

iv) \( \alpha_1 \) is irrational;

v) if \( \alpha = \frac{b_1}{a_1} - \frac{b_2}{a_2} - \frac{b_3}{a_3} \ldots \), where the \( a_i \) and \( b_i \) are positive integers, and if \( a_n \geq b_{n+1} \) for all sufficiently large \( n \), with strict inequality infinitely often, then \( \alpha \) is irrational.

25. i) \( \sum_{k=1}^{n} \frac{1}{c_k} = \frac{1}{c_1} - \frac{c_1^2}{c_1 + c_2} - \frac{c_2^2}{c_2 + c_3} - \ldots - \frac{c_{n-1}^2}{c_{n-1} + c_n} \);

ii) \( \sum_{k=1}^{n} c_k = \frac{c_1}{1} - \frac{c_2}{c_1 + c_2} - \frac{c_3}{c_2 + c_3} - \ldots - \frac{c_n}{c_{n-1} + c_n} \);
iii) $\sum_{k=1}^{\infty} \frac{1}{c_k}, \sum_{k=1}^{\infty} c_k$ converge to $\alpha, \beta$ respectively if and only if the right sides in (i), (ii) converge to $\alpha, \beta$;

iv) from $\frac{1}{e} = \frac{1}{2!} - \frac{1}{3!} + \frac{1}{4!} - \cdots$ deduce

$$e = 2 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2 + \frac{1}{2 + \frac{1}{3 + \frac{1}{3 + \frac{1}{4 + \frac{1}{4 + \cdots}}}}}}}};$$

v) $\frac{\pi}{4} = \frac{1}{1 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{3^2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \cdots}}}}}}}}}$.

26. (Lambert's 1761 proof of the irrationality of $\pi$) Define $f_m(x)$, for each real positive $m$, by:

$$f_m(x) = 1 - \frac{x^2}{2^2 m} + \frac{x^4}{2^4 2! m (m+1)} - \frac{x^6}{2^6 3! m(m+1)(m+2)} + \frac{x^8}{2^8 4! m(m+1)(m+2)(m+3)} - \cdots$$

$$= 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2k}}{2^k k! m(m+1)\cdots(m+k-1)}.$$
Then:

(i) \( f_m(x) \) exists for all \( x \);

\( \frac{f_{m+1}(x)}{f_m(x)} = \left( 1 - \frac{x^2}{2^2 m(m+1)} \right)^{-1} = \frac{1}{1 - \frac{x^2/2^2 m(m+1)}{1 - \frac{x^2/2^2 (m+1)(m+2)}{1 - \frac{x^2/2^2 (m+2)(m+3)}{\ldots}}}} \);

(ii) \( \frac{f_{\frac{1}{2}}(x)}{f_{\frac{1}{2}}(x)} = \frac{1}{1 - \frac{x^2}{3} - \frac{x^2}{5} - \frac{x^2}{7} - \ldots} = \frac{\tan x}{x} \);

(iii) \( \pi \) is not rational, since if \( \pi \) were rational, say \( \frac{\pi}{4} = \frac{m}{n} \) for positive integers \( m \) and \( n \), then

\[ 1 = \frac{m}{n} - \frac{m^2}{3n} - \frac{m^2}{5n} - \frac{m^2}{7n} - \ldots, \]

which is not possible since the right hand side is irrational.

27. (Some irrational and transcendental numbers)

I. If \( \alpha \) is a real number which is a zero of an integral polynomial of degree \( n \) but of no such polynomial of smaller degree then \( \alpha \) is said to be algebraic of degree \( n \).
All numbers algebraic of degree \( > 1 \) are thus irrational. A number which is irrational but not algebraic of any degree is said to be transcendental. A simple cardinality argument may be used to prove the existence of transcendental numbers.

\[ \Box \] Let \( \alpha \) be algebraic of degree \( n \) and let \( f \) be an integral polynomial of degree \( n \) having \( \alpha \) as a zero. Then

i) there is an integral polynomial \( g \) such that \( f(x) = (x - \alpha)g(x) \), \( g(\alpha) \neq 0 \);

ii) there is a positive \( \delta \) such that if \( \alpha - \delta \leq x \leq \alpha + \delta \) then \( g(x) \neq 0 \);

iii) there is a constant \( M \) and integers \( a, b \) with \( b > 0 \) such that

\[
|\alpha - \frac{a}{b}| = \left| \frac{f\left(\frac{a}{b}\right)}{g\left(\frac{a}{b}\right)} \right| \geq \frac{1}{Mb^n};
\]
\( \hat{w} \) (Liouville 1844)

If \( \alpha \) is algebraic of degree \( n \) then there is a positive constant \( c \) such that \( |\alpha - \frac{a}{b}| > \frac{c}{b^{n}} \) for all integral \( a, b \) with \( b > 0 \).

\[ \text{III i) } \alpha = \sum_{m=0}^{\infty} 10^{-2^{m}} \text{ is irrational;} \]

\[ \text{ii) } \text{an irrational number is called a Liouville number if for each positive integer } n \text{ and constant } c > 0 \text{ there is a rational number } \frac{a}{b}, \ b > 0, \text{ such that } |\alpha - \frac{a}{b}| < \frac{c}{b^{n}}. \text{ Every Liouville number is transcendental;} \]

\[ \text{iii) } \alpha = \sum_{m=0}^{\infty} a_{m}10^{-m!} \text{ is transcendental when the } a_{m} \text{ are integers satisfying } |a_{m}| \leq M \text{ for some } M. \]

\[ \text{IV i) let } \alpha = [a_{0}, a_{1}, \ldots] \text{ be an irrational number with convergents } \frac{p_{n}}{q_{n}}; \text{ then if } a_{q+1} > q_{k}^{k} - 1 \text{ for all } k \geq 1, \text{ } \alpha \text{ is transcendental;} \]

\[ \text{ii) using (i) exhibit a transcendental number;} \]

\[ \text{iii) if } a_{q+1} \geq (2^{k}a_{1} \ldots a_{k})^{k-1} \text{ for } k \geq 1 \text{ and } a_{0}, a_{1}, \text{ are arbitrary then } [a_{0}, a_{1}, a_{2}, \ldots] \text{ is transcendental}. \]
28. In this problem \( x \) ranges over the irrational numbers in the interval \([0, 1]\). We write \( x = [0, a_1(x), a_2(x), \ldots] \) so that each \( a_j(x) \) is a positive integer. We denote the probability that \( a_n(x) = k \) by \( P_n k \) and the probability that \( (a_1(x), \ldots, a_t(x)) = (a_1, \ldots, a_t) \) by \( P(a_1, \ldots, a_t) \).

I i) \( \sum_{k=1}^{\infty} P_n k = 1 \) for \( n = 1, 2, \ldots \)

and

\( \sum_{k=1}^{\infty} P(a_1, \ldots, a_{n-1}, k) = P(a_1, \ldots, a_{n-1}) \) for \( n = 2, 3, \ldots \);

ii) \( P_{1k} = \frac{1}{k(k+1)} \);

iii) \( P_{2k} = P_{1k} \sum_{n=1}^{\infty} \frac{1}{(n+\frac{1}{2})(n+\frac{3}{2})} = \frac{\pi^2}{6k(k+1)}(1 - \epsilon_k) \),

where \( \epsilon_k \to 0 \) as \( k \to \infty \);

iv) \( P_{2k} \geq P_{1k} \) for \( k \geq 2 \) but \( P_{21} < P_{11} \).

II Let \( \frac{p_j}{q_j} \), \( 0 \leq j \leq n \), be the convergents to \([0, a_1, \ldots, a_{n-1}, k]\). Then

i) \( P(a_1, \ldots, a_{n-1}, k) = \frac{1}{q_{n-1}^2}(k + \frac{q_{n-2}}{q_{n-1}})(k+1 + \frac{q_{n-2}}{q_{n-1}}) \);
ii) \[ \frac{k}{k+2} < \frac{\mathcal{P}(a_1, \ldots, a_{n-1}, k^n)}{\mathcal{P}(a_1, \ldots, a_{n-1}, k^n)} = \frac{k + \frac{2n-2}{k+1}}{k+2 + \frac{2n-2}{k+1}} < \frac{k+1}{k+3}; \]

iii) \[ \frac{2}{k(k+1)} < \frac{\mathcal{P}(a_1, \ldots, a_{n-1}, k^n)}{\mathcal{P}(a_1, \ldots, a_{n-1}, 1^n)} < \frac{6}{(k+1)(k+2)} \quad \text{for } k \geq 2; \]

iv) \[ 2 = \sum_{k=1}^{\infty} \frac{2}{k(k+1)} < \frac{\mathcal{P}(a_1, \ldots, a_{n-1}, 1^n)}{\mathcal{P}(a_1, \ldots, a_{n-1}, 1^n)} < \sum_{k=1}^{\infty} \frac{6}{(k+1)(k+2)} = 3; \]

v) \[ \frac{2}{3k(k+1)} < \frac{\mathcal{P}(a_1, \ldots, a_{n-1}, k^n)}{\mathcal{P}(a_1, \ldots, a_{n-1}, 1^n)} = \mathcal{P}(k^n) < \frac{3}{(k+1)(k+2)}. \]

\[ \sum_{k=1}^{M} \mathcal{P}(k^n) = \frac{M}{M+1}; \]

\[ \sum_{a_{n-1}}^{M} \mathcal{P}(a_1, \ldots, a_{n-1}, 1^n) < \alpha \mathcal{P}(a_1, \ldots, a_{n-1}), \]

for \( n > 2 \) and where \( 0 < \alpha = 1 - \frac{2}{3(M+1)} < 1; \)

\[ \sum_{a_{n-1}}^{M} \mathcal{P}(a_1, \ldots, a_n) < \alpha^{n-1} \frac{M}{M+1}; \]

\( \frac{[a_0, a_1, a_2, \ldots]}{[a_0, a_1, a_2, \ldots]} \) is the set expansion of a number picked at random from \([0, 1]\) then the set of \( a_1, a_2, \ldots \) is, with probability 1, unbounded; i.e., almost all real numbers fail to have bounded partial quotients.

\[ \text{Let } \Phi \text{ be an arbitrary positive valued function defined over the positive integers and suppose } N \geq 1. \text{ Then} \]

\[ i) \frac{2}{3(\Phi(t)+1)} < \sum_{k \geq \Phi(t)} \frac{\mathcal{P}(a_1, \ldots, a_{k-1}, 1^n)}{\mathcal{P}(a_1, \ldots, a_{k-1})} < \frac{3}{\Phi(t)+1} \text{ for } t > N; \]
\[ ii) \quad 1 - \frac{3}{\varphi(t)+1} < \sum_{1 \leq k < \varphi(t)} \frac{\mathcal{P}(a_1, \ldots, a_{t+1}, k)}{\mathcal{P}(a_1, \ldots, a_{t+1})} < 1 - \frac{2}{3(\varphi(t)+1)} \quad \text{for } t > N; \]
\[ iii) \quad \mathcal{P}(a_1, \ldots, a_N) \prod_{j=1}^{N} \left( 1 - \frac{3}{\varphi(j)+1} \right) < \sum \mathcal{P}(a_1, \ldots, a_t) < \mathcal{P}(a_1, \ldots, a_N) \prod_{j=1}^{N} \left( 1 - \frac{2}{3(\varphi(j)+1)} \right) \quad \text{for } t > N, \]

where the middle sum is over all \((t-N)\)-tuples \((a_{N+1}, \ldots, a_t)\) such that \(1 \leq a_j < \varphi(j), N < j \leq t;\)

iv) if \(\sum_{n=1}^{\infty} \frac{1}{\varphi(n)}\) diverges, respectively converges, then the probability that a random \(x\) in \([0,1]\) satisfies \(a_n(x) < \varphi(n)\) for all sufficiently large \(n\) is \(0\), respectively \(1\).

\textbf{Remarks.}

1. The particular approach to continued fractions, via Euler brackets, as presented here is somewhat unusual. Chrystal [1904] gives a more complete discussion of Euler brackets than we have given. A particularly nice geometrical introduction to continued fractions is given by Stark [1970].
2. The treatment of Farey fractions, see #9, follows byxwtaδ [1966] and, in fact, our exposition in many parts of this chapter owes much to the same source.

3. For #21 see Klein [1924] or Davenport [1952].

4. In connection with #23 one might consult Matthews, Walters [1970].

5. The details in #25 will be found in Cheney [1966].

6. The natural continuation of #28 would be to prove Kuzmin's theorem which states that for almost all real numbers \( x \),

\[
\sqrt[n]{a_1(x)} \cdots a_n(x) \to \prod_{k=1}^{\infty} \left( 1 + \frac{1}{k(k+2)} \right)^{\frac{\ln k}{\ln^2}}
\]

where it will be noted that the limit is an absolute constant. For good expositions of this theorem,
along entirely separate lines, the reader might consult Khinchin [1964] and/or Kac [1959]. The second of these gives a very interesting account of the theorem connecting it with statistical mechanics and the ergodic theorem.

7. The most complete treatment of all aspects of continued fractions will be found in Perron [1954].
1. (Bonse inequality.) Let \( p_1, p_2, \ldots \) be the primes in their natural order and suppose \( n \geq 10 \). Further, let \( j \) satisfy \( 2 \leq j \leq n-1 \) and set
\[
N_1 = p_1 \cdots p_{j-1}, N_2 = 2 p_1 \cdots p_{j-1}, N_3 = 3 p_1 \cdots p_{j-1},
\]
\[
\cdots, \quad N_{p_j} = p_j p_1 \cdots p_{j-1}.
\]

Then:

i) each of \( p_j, \ldots, p_n \) divides at most one of \( N_1, \ldots, N_{p_j} \);

ii) there is a \( j \), \( 2 \leq j \leq n-1 \), for which
\[
N_j > n - j + 1;
\]

iii) letting \( i \) be the smallest \( j \) for which
\[
N_j > n - j + 1,
\]
there is a \( k \), \( 1 \leq k \leq p_i \), such that \( p_1, \ldots, p_n \) all fail to divide \( kp_1 \cdots p_{i-1} \) and, therefore, \( p_{n+i} < p_1 \cdots p_i \);

iv) the \( i \) in (iii) exceeds 4 so \( p_{i-2} \geq i \) and \( p_1 \cdots p_i < p_{i+1} \cdots p_n \);

v) for \( n \geq 4 \), \( p_{n+i} < p_1 \cdots p_n \).
2. (A property of 30)

Suppose \( p_k \leq \sqrt{n} < p_{k+1} \), where \( p_k \) is again the \( k \)th prime number. Then:

i) if for some \( j \leq k \), \( p_j \) does not divide \( n \) then \( (p_j^2, n) = 1 \) and \( p_j^2 < n \);

ii) if no composite integer \( < n \) is prime to \( n \) then \( p_1 \cdots p_k | n \) and, therefore, \( p_1 \cdots p_k \leq n \);

iii) if \( n \geq 49 \) there is a composite integer \( < n \) and prime to \( n \);

iv) all positive integers \( > 1 \) and \( < 30 \) which are prime to 30 are themselves prime and no integer larger than 30 has this property.

3. (A property of 24)

The number 24 is the largest integer which is divisible by every positive integer smaller than its square root.
4. (Erdős) We write \( \pi(x) \) for the number of primes \( \leq x \) and \( N_j(x) \) for the number of positive integers not exceeding \( x \) having no prime factor \( > j \), the \( j \)th prime number.

Then:

i) every integer having no prime factor \( > j \) is of the form \( m^2 p_1^{e_1} \cdots p_j^{e_j} \), where each \( e_i \) is 0 or 1;

ii) \( N_j(n) \leq \sqrt{n} \cdot 2^j \);

iii) \( \pi(n) \geq \ln n / 2 \ln 2 \) and, therefore, the number of primes is not finite;

iv) \( p_n < 4^n \);

v) the series \( \sum_{n=1}^{\infty} \frac{1}{p_n} \) diverges, since otherwise there is a \( j \) such that

\[
2^j \sqrt{x} \geq N_j(x) \geq x - \sum_{n \geq j} \left[ \frac{x}{j} \right] \geq x - \sum_{n \geq j} \frac{x}{p_n} > \frac{x}{2}.
\]

5. (Sierpinski 1953)

\[
\pi(x) = 1 + \sum_{k=3}^{[x]} \left\{ 1 - \lim_{m \to \infty} \left( 1 - \frac{k^{-1}}{m} \left( \sin \frac{k \pi}{j} \right)^2 \right)^m \right\}.
\]
6. (Hardy 1906) Let $\mathcal{D}(n)$ be the largest prime factor of $n$. Then
$$
\mathcal{D}(n) = \lim_{s \to \infty} \lim_{m \to \infty} \lim_{k \to \infty} \sum_{j=0}^{m} \left\{ 1 - \left(\cos \left(\frac{(j+1)s}{n}\right)^2 \right)^k \right\}.
$$

7. (Moser 1950) Let $p_n$ be the $n^{th}$ prime.
Then:
   \begin{enumerate}
   \item $\sum_{m=1}^{\infty} p_m 10^{-\frac{m(m+1)}{2}}$ converges to $\beta_k$, $k \geq 0$,
   \item $p_n = \left[ 10^{\frac{n(n+1)}{2}} \beta_o \right] - 10^n \left[ 10^{\frac{n(n-1)}{2}} \beta_o \right]$.
   \end{enumerate}

8. (Sierpinski 1952) Let $p_n$ be the $n^{th}$ prime.
Then:
   \begin{enumerate}
   \item $\sum_{m=k+1}^{\infty} p_m 10^{-2^m}$ converges to $\alpha_k$, $k \geq 0$, where
   \item $0 < \alpha_k < 10^{-2^k}$
   \item $p_n = \left[ 10^{2^n} \alpha_o \right] - 10^{2^n-1} \left[ 10^{2^n-1} \alpha_o \right]$.
   \end{enumerate}

9. (Härtter 1961) Let $A = \{a_1, a_2, \ldots\}$ be an arbitrary monotone increasing sequence, $a_n \leq a_{n+1}$, of positive integers. Then:
i) there is a numerical function $f$ satisfying:
   a) $f(n)/f(i)$ is an integer for all $i \leq n$;
   b) $\sum_{v=n+1}^{\infty} \frac{a_v}{f(v)}$ converges to a value $< \frac{1}{f(n)}$ for $n \geq 0$;

ii) for any function $f$ satisfying (a), (b) of (i)
   
   $a_n = \left[ f(n) \alpha \right] - \frac{f(n)}{f(n-1)} \left[ f(n-1) \alpha \right]$,

   where $\alpha = \sum_{v=1}^{\infty} \frac{a_v}{f(v)}$;

iii) the results in \#7, \#8 are special cases of (ii).

10. (Chebyshev) Let $n \geq 2$ be given. Then:

   i) $2^n < \binom{2n}{n} < 2^{2n}$;

   ii) $\prod_{p \leq 2n} p$ divides $\binom{2n}{n}$ which, in turn, divides

   $\prod_{p \leq 2n} p^{t_p}$, where $t_p = \left[ \frac{\ln 2n}{\ln p} \right]$;

   iii) a) $2^n < \prod_{p < 2n} p^{t_p}$;

   b) $\prod_{p \leq 2n} p < 2^{2n}$;

   iv) $\sum_{p \leq x} \ln p \geq \frac{1}{2} \left( \Pi(x) - \sqrt{x} \right) \ln x$ and, therefore, $\Pi(x) \leq \frac{2}{\ln x} \sum_{p \leq x} \ln p + \sqrt{x}$;

   v) from (iii-a), $\Pi(2n) > \frac{n \ln 2}{\ln 2n}$ and, therefore, there exists a constant $A$ such that $\Pi(x) > A \frac{x}{\ln x}$ for all $x \geq 2$. 
vi) from \((iii-b)\), \(\sum_{p \leq x} \ln p < 2n \ln n + \sum_{p \leq x} \ln p\), and, therefore, \(\sum_{p \leq x} \ln p < 2^{k+1}\);

vii) there exists a positive constant \(A\) such that \(\sum_{p \leq x} \ln p < A x\) for all \(x \geq 2\);

viii) there exists a positive constant \(A\) such that \(\pi(x) < A \frac{x}{\ln x}\) for all \(x \geq 2\);

ix) (Chebyshev 1852) for \(x \geq 2\) and suitable positive constants \(A\) and \(B\),

\[ A \frac{x}{\ln x} < \pi(x) < B \frac{x}{\ln x}. \]

11. (Approximate order of \(\pi_n\))

Let \(\varepsilon > 0\) be given. Then:

i) from Chebyshev's inequality there is an \(x_0\) such that \(1 - \varepsilon < \frac{\ln \pi(x)}{\ln x} < 1 + \varepsilon\) for \(x > x_0\);

ii) for suitable positive constants \(A\) and \(B\) and for \(x > x_0\),

\[ A (1 - \varepsilon) \frac{\pi(x) \ln \pi(x)}{x} < B (1 + \varepsilon); \]

iii) for \(n\) sufficiently large

\[ A (1 - \varepsilon) \frac{n \ln n}{P_n} < B (1 + \varepsilon); \]
iv) (Theorem) There exist positive constants $A$ and $B$ such that

$$A \ln n < p_n < B \ln n ;$$

v) from (iv) one easily deduces that the series $\sum_{j=1}^{\infty} \frac{1}{p_j^\alpha}$ is divergent for $\alpha \leq 1$ and convergent for $\alpha > 1$.

12. (Bertrand) Let $P_n = \prod_{p \leq 2n} p$, where $P_n = 1$ when there are no primes between $n$ and $2n$.

Then:

i) $P_n < \left(\frac{2n-1}{n}\right) < 4^{n-1}$ for $n \geq 2$ ;

ii) $\prod_{\frac{4^n}{2\sqrt{n}}} p < 4^n$ for all real $x \geq 2$ ;

iii) if $2 \leq \frac{2n}{3} < p \leq n$ then $p$ does not divide $\frac{2n}{n}$ ;

iv) $\frac{4^n}{2\sqrt{n}} < \left(\frac{2n}{n}\right) \leq (2n)^{\frac{4}{\sqrt{4n}}} 4^{\frac{2n}{3}} P_n$ for $n \geq 3$ ;

v) $P_n > 1$ if $4^{2n} > 8 (2n)^{3\sqrt{2n}+3}$ ;

vi) $P_n > 1$ if $n > 500$ ;

vii) (Bertrand) if $n \geq 2$ there is a prime strictly between $n$ and $2n$ ;

viii) $p_{n+1} < 2p_n$ if $n \geq 1$. 
13. (Finsler) Let $P_n$ be as in #12. Then from #12(iv), $P_n > \frac{4^{n/3}}{2\sqrt{n}(2n)^{1/2}\sqrt{\pi}}$. Setting the right side of this inequality equal to $(2n)^x$ we have

i) $x < \Pi(2n) - \Pi(n)$ if $n \geq 3$;

ii) $x \ln 2n = \frac{n}{3} \left( \ln 4 - \frac{3\ln 4n}{2n} - \frac{3\ln 2n}{\sqrt{\pi}} \right) > \frac{n}{3}$ if $n \geq 2500$;

iii) $\frac{n}{3\ln 2n} < \Pi(2n) - \Pi(n)$ if $n \geq 2500$;

iv) $\Pi(2n) - \Pi(n) < \frac{7n}{5\ln n}$ if $n \geq 2$;

v) (Finsler) if $n \geq 2$ then

$\frac{n}{3\ln 2n} < \Pi(2n) - \Pi(n) < \frac{7n}{5\ln n}$;

vi) $\Pi(2n) - \Pi(n) \geq 2$ if $n \geq 6$;

vii) $P_{n+2} < 2P_n$ if $n \geq 4$;

viii) there is a prime $p$ satisfying $n < p < 2n - 2$ if $n \geq 4$; though not equivalent to #12(vii) this is sometimes referred to as Bertrand's postulate;

ix) $\Pi(2n) - \Pi(n)$ is an unboundedly increasing function of $n$. 
14. Starting with Finsler's theorem (*13-v) one finds:

i) \[ \pi(2^k) < \frac{2^{k+1}}{k \ln 2} \text{ if } k \geq 1; \]

ii) \[ \pi(n) < 4 \frac{n}{\ln n} \text{ if } n \geq 2; \]

iii) \[ \frac{1}{12} \frac{n}{\ln n} < \pi(n) - 1 \text{ if } n \geq 2; \]

w) (Chebyshev's theorem again)

\[ \frac{1}{12} \frac{x}{\ln x} < \pi(x) < 4 \frac{x}{\ln x}. \]

(These values of the positive constants in Chebyshev’s theorem are far from “best possible.”)

15. Consider

(\(*\) \[ \pi(mn) > \pi(m) + \pi(n). \]

i) Using \(*\)14(w) (Chebyshev) it is easy to prove (\(*\)) for \(192 \leq n \leq m; \)

ii) using \(*\)13(v) (Finsler) one obtains (\(*\)) for \(2 \leq n \leq 192, 4000 \leq m; \)

(using tables and a computer one gets (\(*\)) for \(2 \leq n \leq m, 6 \leq m; \) see Trost [1968].)
16. (Assuming the result in the parenthetical remark of \#15.)

i) \( \Pi(p_m p_n) > \Pi(p_{m+n}) \) for \( 2 \leq n \leq m, 4 \leq m \);

ii) \( p_m p_n > p_{m+n} \) for \( 1 \leq n, 1 \leq m \);

iii) \( p_{n-1} p_j > p_{n+1} \) for \( 1 \leq j \leq n \);

iv) \( p_{n+1}^n < (p_1 \ldots p_n)^2 \) when \( n \geq 1 \).

17. (A special case of Dirichlet's theorem on primes in arithmetic progressions.)

Put \( F_n(x) = \prod_{\substack{k=1 \atop (k, n)=1}}^n (x - e^{2\pi i k/n}) \), \( n \geq 1 \).

Then:

i) \( x^n - 1 = \prod_{d \mid n} F_d(x) \);

ii) \( F_n(x) \) is an integral polynomial of degree \( \varphi(n) \);

iii) \( F_n(0) = 1 \) for \( n > 1 \);

iv) if \( p \) is a prime factor of \( F_n(a) \), \( n > 1 \), then \( (a, p) = 1 \);
v) if \( p \mid F_n(a) \) and \( t \) is the smallest positive \( n \) for which \( p \mid a^n - 1 \) then:

a) \( t \mid n \);

b) \( t < n \) implies \( a^n - 1 \equiv (a + p)^n - 1 \equiv 0 \pmod{p^2} \);

c) \( t < n \) implies \( p \mid n \);

d) \( p \mid n \) implies \( t = n \) implies \( p \equiv 1 \pmod{n} \);

vi) let \( p_1, \ldots, p_k \) be any finite set of primes; then for \( y \) sufficiently large and \( n > 1 \),
\[
F_n(nyp_1 \cdots p_k) > 1 \quad \text{and} \quad F_n(nyp_1 \cdots p_k) \equiv F_1(0) \equiv 1 \pmod{np_1 \cdots p_k};
\]
thus there is a prime \( p \neq p_j, 1 \leq j \leq k \), satisfying \( p \equiv 1 \pmod{n} \);

vii) for \( n > 1 \) there are infinitely many primes in the arithmetic progression
\[
1, 1 + n, 1 + 2n, 1 + 3n, \ldots.
\]

18. Let \( F_n(x) \) be as in *17 and let \( p \) be a prime. Further, suppose \( n \) has exactly \( r \) distinct prime factors and that \( A_j, 1 \leq j \leq r \), is the
set of products of j of the r primes entering into n. We put
\[ q(x) = \prod_{\alpha \in A_1} (x^{n/\alpha} - 1) \prod_{\alpha \in A_3} (x^{n/\alpha} - 1) \cdots \]
\[ f(x) = (x^n - 1) \prod_{\alpha \in A_2} (x^{n/\alpha} - 1) \prod_{\alpha \in A_4} (x^{n/\alpha} - 1) \cdots \]
and \( e_m = e^{2\pi i m/n} \), with \((m, n) = d\).

i) \( e_m \) is a zero of order 1 of each \( x^{n/\alpha} - 1 \) for which \( \alpha | m \) and is not a zero of all other \( x^{n/\alpha} - 1 \);

ii) if \( d > 1 \) and has \( s \) distinct prime factors, then the highest power of \( x - e_m \) in \( q(x) \) (respectively \( f(x) \)) is \( \left( \text{\( s \) \( \sum \frac{s}{i} \) } \right) + \left( \text{\( \frac{s}{3} \) } \right) + \left( \text{\( \frac{s}{5} \) } \right) + \cdots \) (respectively \( 1 + \left( \text{\( \frac{s}{2} \) } \right) + \left( \text{\( \frac{s}{4} \) } \right) + \cdots \) );

iii) \[ F_n(x) = \frac{(x^n - 1) \prod_{j \text{ even} \text{\( \alpha \in A_j \)}} (x^{n/\alpha} - 1)}{\prod_{j \text{ odd} \text{\( \alpha \in A_j \)}} (x^{n/\alpha} - 1)} \];

iv) if \( p | n \) then \( F_{np}(x) = F_n(x^p) \);

v) if \( p \nmid n \) then \( F_{np}(x) = \frac{F_n(x^p)}{F_n(x)} \);

vi) \[ F_p(x) = \frac{x^{p-1}}{x-1} = x^{p-1} + x^{p-2} + \cdots + x + 1 \];
\[ F_n(1) = \begin{cases} 0 & \text{if } n = 1; \\ \varphi & \text{if } n \text{ is a power of } \varphi; \\ 1 & \text{if } n \text{ has at least 2 distinct prime factors}; \end{cases} \]

\[ F_n(x) = \prod_{d \mid n} (x^{\frac{n}{d}} - 1)^{\mu(d)}, \] where \( \mu \) is the number theoretic function defined by \( \mu(1) = 1, \mu(n) = 0 \) if \( n \) contains as a factor the square of any prime, \( \mu(n) = (-1)^k \) if \( n \) is a product of \( k \) distinct primes;

(i x) let \( n = p_1 \ldots p_t \), where \( t \) is odd and the \( p_i \) are primes satisfying \( p_1 < p_2 < \ldots < p_t \) and \( p_1 + p_2 > p_t \) (see \#13-ix) ; then

\[ F_n(x) \equiv \frac{1}{1-x} \prod_{i=1}^{t} (1-x^{p_i}) \]

\[ \equiv (1+x+\cdots+x^{p_t-1})(1-x^{p_1})\cdots(1-x^{p_{t-1}}) \]

\[ \equiv (1+x+\cdots+x^{p_t-1})(1-x^{p_1}-x^{p_2}-\cdots-x^{p_{t-1}}) \pmod{x^{p_t+1}}; \]

x)(Schur 1931) for \( n \) as in (ix) the coefficient of \( x^{p_t} \) in \( F_n(x) \) has absolute value \( t-1 \).
19. (Richert) Let $S_n$ be the set of sums of 2 or more of the first $n$ primes, no repetitions permitted. Then:

i) all integers between 12 and 29 (note $29 = 12 + p_7$), inclusive, are in $S_6$;

ii) if $n \geq 7$ all integers between 12 and $29 + p_7 + \cdots + p_n$ are in $S_n$;

iii) all integers $\geq 12$ are sums of 2 or more distinct primes;

iv) all integers $\geq 7$ are either prime or a sum of two or more distinct primes;

v) 6 is the largest positive integer which is neither a prime nor the sum of two or more distinct primes and 11 is the largest positive integer not the sum of two or more distinct primes.

20. (Furstenberg) Let $S$ be the set of all integers. Take as a basis for a topology in
S the collection of all two way infinite arithmetic progressions. Thus a set of S is open if it is the union of such arithmetic progressions.

i) S with the specified basis is a topological space;

ii) each arithmetic progression is both open and closed;

iii) each finite union of arithmetic progressions is closed;

iv) if \( A_p = \{0, \pm p, \pm 2p, \cdots\} \), where \( p \) is a prime, and if \( A = \biguplus_p A_p \), then the complement of \( A \) is \( \{-1, 1\} \);

v) that there are infinitely many primes follows from (iv).

21. (Nicol) For each positive real number \( x \) let \( \Pi_2(x) \) denote the number of twin primes \((p, p+2)\) with \( p \leq x \). Then
\[
\pi_2(x) = 2 + \sum_{n \leq x} \sin \left\{ \frac{n+2}{2} \left[ \frac{n}{n+2} \right] \right\} \sin \left\{ \frac{n}{2} \left[ \frac{n}{n+2} \right] \right\},
\]
where \( \left\lfloor \cdots \right\rfloor \) is the largest integer not exceeding \( \cdots \).

22. (Williams [1964])

Define \( F(n) \) by \( F(n) = \left\lfloor \cos^2 \pi \frac{(n-1)!+1}{n} \right\rfloor. \) Then:

i) \( F(n) = \begin{cases} 
1 & \text{for } n \text{ prime or } n = 1; \\
0 & \text{for } n \text{ composite}; 
\end{cases} \)

ii) the \( n^{th} \) prime \( p_n \) is given by

\[
p_n = 1 + \sum_{m=1}^{\pi(n)} \left[ \frac{n}{\sum_{k=1}^{F(k)}} \right].
\]

Remarks.

1. The Bonse inequality in \#1 is not very strong and its main interest is in the simplicity of its proof and its application to problems \#2, 3. The property of 30 given in \#2 goes back to Schatunovsky who proved it in 1893.
Generalizations have been given—see e.g. Dickson I [1952] pp. 132, 133, 137, 138 and Landau I [1909] pp. 229-234.

2. For other work on prime representing functions, #7-9, one might consult Namboodiripad [1971], Willans [1964], Sato & Straus [1970], Dudley [1969], Mills [1947], and the references therein.

3. Problem #4 is due to Erdös [1938], #13 to Finsler [1945], #19 to Richert [1941], #20 to Furstenberg [1955], #21 to Nicol [1974], #22 to Willans [1964]. For an exposition of the results in #12-16 see Trost [1968]. Expositions of the special case of Dirichlet’s theorem may be found in Nagell [1951] and Landau [1909]. A simple, even more elementary, proof is given in Niven, Powell [1976]. A complete proof of Dirichlet’s theorem is given in xxiv.
4. Taking $n \geq 4$ #16(w) yields $p_{n+1} \leq p_{n+1}^{n/2} < p_1 \cdots p_n$, which is the Bonse inequality of #1. As with the property of 30 one can use #16(w) to prove that when $n > p_k^k$ then there is a $t$, $1 \leq t \leq 2k$, such that $p_t, p_t^2, \ldots , p_t^k$ are all prime to $n$ and smaller than $n$. With $k = 2$ we see all numbers $n \geq p_4^2 = 49$ are prime to a smaller composite number.

5. The polynomials $F_n(x)$ introduced in #17 are called cyclotomic polynomials. This particular use of these polynomials goes back to Bang and Sylvester in the late 1880's. The general Dirichlet theorem was first proved by "non-elementary" means by Dirichlet in 1837. The cyclotomic polynomials offer another of those curious instances where intuitive induction may lead one astray.
The first ten cyclotomic polynomials are:

\[ F_1(x) = x - 1 \quad F_6(x) = x^2 - x + 1 \]
\[ F_2(x) = x + 1 \quad F_7(x) = x^6 + x^5 + x^4 + x^3 + x^2 + x + 1 \]
\[ F_3(x) = x^2 + x + 1 \quad F_8(x) = x^4 + 1 \]
\[ F_4(x) = x^2 + 1 \quad F_9(x) = x^6 + x^3 + 1 \]
\[ F_5(x) = x^4 + x^3 + x^2 + x + 1 \quad F_{10}(x) = x^4 - x^3 + x^2 - x + 1. \]

Even this small sample of data might lead one to conjecture that all non-zero coefficients of \( F_n(x) \) are 1 or -1. Further data up to \( n = 104 \) would support this conjecture.

However, for \( n = 105 \) a coefficient 2 appears.

If one lets \( A_n \) be the largest modulus of a coefficient of \( F_n(x) \) then as Schur proved in 1931 (see \( \pi_8(x) \)), \( \limsup A_n = \infty \). (See I. Schur, Gesammelte Abhandlungen III p. 460-1.)

This was sharpened by Emma Lehmer [1936] and then later Erdős [1946] proved that for every \( k \) there are infinitely many \( n \) for which \( A_n > n^k \).
There is a continuing interest in these matters and the reader might see Zeitlin [1968] and/or Beiter [1971].

6. Similar results to that of §19 may be found in Dressler [1972,3] and the references contained therein.
xv Quaternions, Complex Numbers, e~
Sums of 4 and 2 Squares

1. (Quaternions)

Let \( R \) and \( \mathbb{C} \) stand for the fields of real and complex numbers respectively and let

\[
R' = \left\{ \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \mid a \text{ and } b \text{ are in } R \right\};
\]

\[
R'' = \left\{ \begin{pmatrix} a & -b & c & -d \\ b & a & -d & c \\ c & d & a & -b \\ d & -c & b & a \end{pmatrix} \mid a, b, c, \text{ and } d \text{ are in } R \right\};
\]

\[
\mathbb{C}' = \left\{ \begin{pmatrix} a & b \\ -b & \overline{a} \end{pmatrix} \mid a \text{ and } b \text{ are in } \mathbb{C} \right\}, \quad \text{where}
\]

\( \overline{c} \) is the ordinary complex conjugate of \( c \).

In \( R'' \) we write \( 1, i, j, k \) for the elements

\[
\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}
\]

respectively.
with the usual operations of matrix addition and multiplication:

i) $C'$ is a non-commutative field with $R$ a subfield;

ii) $R'$ is isomorphic to $C$;

iii) $C'$ is isomorphic to $R''$;

iv) $R''$ is a 4 dimensional vector space over $R$;

v) the set $Q$ of all rational linear combinations of $1, i, j, k$ is a non-commutative subfield of $R''$;

vi) multiplication in $R''$ and in $Q$ (see (v)) is characterized by the equations $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$ and the fact that $1$ is a multiplicative identity.

Elements of $Q$ are called rational quaternions while elements of $R''$ are called real quaternions.
2. (Conjugate, Trace, Norm)

If \( \alpha = a + ib + jc + kd \) is a quaternion (real or rational) we put \( \overline{\alpha} = a - ib - jc - kd \),
\( T\alpha = 2a \), \( N\alpha = a^2 + b^2 + c^2 + d^2 \) and call these the conjugate, trace, and norm of \( \alpha \), respectively.

i) \( \alpha = \overline{\alpha} \) if and only if \( b = c = d = 0 \);

ii) \( N\alpha = N\overline{\alpha} \) and \( T\alpha = \alpha + \overline{\alpha} \);

iii) \( N\alpha = 0 \) if and only if \( \alpha = 0 \);

iv) \( \overline{\alpha + \beta} = \overline{\alpha} + \overline{\beta} \);

v) \( \overline{\alpha \beta} = \overline{\beta} \overline{\alpha} \);

vi) \( N\alpha = \alpha \overline{\alpha} \);

vii) \( N(\alpha\beta) = (N\alpha)(N\beta) \);

viii) each of \( \alpha, \overline{\alpha} \) satisfies the equation \( x^2 - xT\alpha + N\alpha = 0 \); this equation is called the principal equation for \( \alpha \).
3. (Integral Quaternions)

In this problem we deal exclusively with rational quaternions, i.e. with elements of \( Q \) (see §1(v)). We use \( \mathbb{Z} \) for the set of rational integers and call an element of \( Q \) integral if it is a zero of a monic polynomial with rational integer coefficients. We put
\[
\rho = \frac{1}{2}(1+i+j+k)
\]
and define \( L, H, I \) by:
\[
L = \{ a + ib + jc + kd \mid a, b, c, d \text{ are in } \mathbb{Z} \};
\]
\[
H = L \cup \{ \rho + \alpha \mid \alpha \text{ is in } L \};
\]
\[
I = \text{set of all integral quaternions}.
\]

i) \( \alpha \) is in \( I \) if and only if \( T\alpha \) and \( N\alpha \) are in \( \mathbb{Z} \);

ii) \( L \subseteq H \subseteq I \);

iii) If \( A \) is either \( L \) or \( H \) and if \( \alpha \in A \) then \( \overline{\alpha} \), \( i\alpha \), \( j\alpha \), \( k\alpha \) are in \( A \);

iv) \( I \) is not closed under multiplication, not even under left multiplication by \( i \);
v) \( \mathcal{L} \) and \( \mathcal{H} \) are integral domains while \( I \) is not;

vi) \( \mathcal{H} \) is a maximal integral domain in \( I \);

vii) \( \mathcal{H} = \{a \alpha + i b + j c + k d \mid a, b, c, d \text{ are in } \mathbb{Z}\} \).

We call \( \mathcal{L} \) the Lipschitz' and \( \mathcal{H} \) the Hurwitz' integral subdomain of \( \mathbb{Q} \). In the following problems all quaternions unless stated specifically to the contrary are to be taken from \( \mathcal{H} \). When noted they may often be even more restricted and be taken from \( \mathcal{L} \). We systematically use small Greek letters for quaternions.

A quaternion \( \alpha \) is called a unit if \( N\alpha = 1 \). If \( \alpha = \beta \gamma \) we call \( \beta \) a left divisor of \( \alpha \) and if \( \alpha = \gamma \beta \) we call \( \beta \) a right divisor of \( \alpha \). If there are units \( \nu \), \( \eta \) such that \( \alpha = \eta \beta \nu \) we call \( \alpha \) and \( \beta \) associates. If \( \eta = 1 \) we call \( \beta \) a left associate of \( \alpha \).
A common left divisor of $\alpha$ and $\beta$ which is left divisible by every common left divisor of $\alpha$ and $\beta$ is called a left \textit{gcd} of $\alpha$ and $\beta$. In $\S$4(v) below it is shown that left gcd's always exist. For each $\alpha, \beta$ we let $(\alpha, \beta)$ denote one such gcd of $\alpha$ and $\beta$.

4. \(i\) Every element $\alpha$ has a left associate in $\mathcal{L}$;

\(ii\) given $m \in \mathbb{Z}$ and $\alpha \in \mathcal{H}$ there is a $\beta \in \mathcal{H}$ such that $N(\alpha - m\beta) < m^2$; i.e. every "open circle" of radius $m^2$ contains an element of $\mathcal{H}$ which is divisible by $m$;

\(iii\) (analogue of the Euclidean algorithm) if $\alpha$ and $\beta$ are in $\mathcal{H}$, $\beta \neq 0$, then there exist $y_1, \delta_1, y_2, \delta_2$ in $\mathcal{H}$ such that

$$\alpha = \beta y_1 + \delta_1, \quad N\delta_1 < N\beta;$$

$$\alpha = y_2 \beta + \delta_2, \quad N\delta_2 < N\beta;$$
iv) if $\mathfrak{d}$ is a left gcd of two quaternions then $\mathfrak{d}$ is a left gcd of these quaternions if and only if $\mathfrak{d}$ and $\mathfrak{d}'$ are left associates;

v) for fixed $\alpha, \beta$ in $H$ if $\mathfrak{d}$ is an element of $A = \{ \alpha n + \beta v \mid n, v \in H \}$ such that

$$ 0 < N\mathfrak{d} \leq N\mathfrak{d}' \text{ for all } \mathfrak{d}' \in A $$

then $\mathfrak{d}$ is a left gcd of $\alpha$ and $\beta$;

vi) there are exactly 24 units in $H$ and each of them is a two sided divisor of all elements of $H$; there are exactly 8 units in $I$ and they are $\pm 1, \pm i, \pm j, \pm k$;

vii) if $n$ is a rational integer $> 1$ and $n$ divides $N\alpha$ then $(\alpha, n)$ is not a unit.

5. (Primes)

An element $\alpha$ in $H$ is called composite if it may be written as the product of two elements of $H$ each having norm $> 1$. Non-zero elements of $H$ which are neither units
nor composite are called prime. If \( \alpha \) in \( \mathcal{H} \) has no rational integer divisor other than \( \pm 1 \), then \( \alpha \) is said to be primitive.

i) All associates of a prime are prime;

ii) If \( N\alpha \) is a rational prime then \( \alpha \) is a prime in \( \mathcal{H} \);

iii) If \( \beta \) is a rational prime dividing the norm of a primitive \( \alpha \) then \( (\alpha, \beta) \) is prime in \( \mathcal{H} \) and \( N((\alpha, \beta)) = \beta \);

iv) Every rational prime is the norm of a prime in \( \mathcal{H} \) and, therefore, is not a prime in \( \mathcal{H} \);

v) \( N\alpha \) is a rational prime if and only if \( \alpha \) is prime in \( \mathcal{H} \);

vi) If \( 2 \) divides \( N\alpha \), then \( \alpha = (1+i)^r m \beta \), for suitable \( \beta \) in \( \mathcal{H} \);

vii) Every element \( \alpha \) in \( \mathcal{H} \) may be written in the form \( \alpha = (1+i)^r m \beta \), where \( r, m \) are non-negative rational integers, \( r = 0 \) or \( 1 \), \( \mathcal{N} \) is a unit in \( \mathcal{H} \), and \( \beta \) is a primitive element of \( \mathcal{L} \) of odd norm;
viii) suppose $\alpha$ and $\gamma$ are primitive and $N\alpha = 2^r N\gamma$, $N\gamma = p_1 \cdots p_s$, where $p_1, \ldots, p_s$ are odd primes in $\mathbb{Z}$ (not necessarily distinct); then there exist primes $\pi_1, \ldots, \pi_s$ in $\mathcal{H}$ such that $N\pi_t = p_t$, $1 \leq t \leq s$, and $\gamma = \pi_1 \cdots \pi_s$,

$\alpha = (1+i)^r \pi_1 \cdots \pi_s$;

ix) for $\alpha$, $N\alpha$ as in (viii), if $\alpha = (1+i)^r \tau_1 \cdots \tau_s$, where the $\tau_s$ are primes in $\mathcal{H}$ and $N\tau_t = p_t$, $1 \leq t \leq s$, then for each $t$, $\tau_t$ and $\pi_t$ are associates;

x) if $\alpha$ is a primitive element of $\mathcal{H}$ and $N\alpha = 2^r p_1 \cdots p_s$, where the $p_j$ are odd primes and $r = 0$ or $1$, then there exist unique, up to associates, primes $\pi_1, \ldots, \pi_s$ in $\mathcal{H}$ such that $\alpha = (1+i)^r \pi_1 \cdots \pi_s$, $N\pi_j = p_j$ for $1 \leq j \leq s$;

xi) non-primitive elements of $\mathcal{H}$ may have distinct prime factorizations.
6. (Number of quaternions with given norm)

i) The number of quaternions with norm 2 is exactly 24 and they are all in \( \mathbb{L} \);

ii) in this part let \( p \) be an odd prime in \( \mathbb{Z} \) and suppose \( A, B, C, D \) are integers (mod \( p \)) in \( \mathbb{Z} \). Then:

a) given \( a, b \) in \( \mathbb{Z} \) the congruences

1) \( A^2 + B^2 + C^2 + D^2 \equiv 0 \) (mod \( p \)) and

2) \( A^2 + (-aA + B)^2 + (-6A + C)^2 + D^2 \equiv 0 \) (mod \( p \))

have the same number of solutions \( A, B, C, D \);

b) \( a, b \) may be chosen so that \( p \) divides \( 1 + a^2 + b^2 \) and (2) of (a) becomes

3) \( B^2 + C^2 + D^2 \equiv 2A(aB + bC) \) (mod \( p \));

c) if in (3), \( aB + bC \equiv 0 \) (mod \( p \)) then there are \( p \) solutions when \( B \equiv C \equiv 0 \) (mod \( p \))

and \( 2p(p-1) \) solutions otherwise;

d) if in (3), \( aB + bC \not\equiv 0 \) (mod \( p \)) then there are \( p(p^2-p) \) solutions;
e) the number of solutions of (1), and therefore the number (modulo p) of $\alpha$'s in $L$ such that $N\alpha \equiv 0 \pmod{p}$ is $(p^2-1)(p+1)+1$.

\[ \beta \] In this part we write $i = i_1, j = i_2, k = i_3$ and suppose all subscripts larger than 3 to be reduced modulo 3. Thus $i_4 = i_1, a_5 = a_2, x_4 = x_1$, etc. Further, $p$ is an odd prime in $\mathbb{Z}$, $\alpha = a_0 + i_1 a_1 + i_2 a_2 + i_3 a_3$ is in $L$, and $p$ divides $N\alpha$ but does not divide $\alpha$.

a) There is a $\nu$, $1 \leq \nu \leq 3$, such that $p$ does not divide $a_0^2 + a_\nu^2$;

b) For $\nu$ as in (a) and $x = x_0 + i_1 x_1 + i_2 x_2 + i_3 x_3$ in $L$ define $\beta = a_0 + a_\nu i_\nu, \eta = x_0 + x_\nu i_\nu, \gamma = a_{\nu+1} + a_{\nu+2} i_\nu, \xi = x_{\nu+1} + x_{\nu+2} i_\nu$;

then

1) $\alpha = \beta + \gamma i_{\nu+1}, x = \eta + \xi i_{\nu+1}$;

2) if $a, b, c, d$ are scalars then $a + bi\nu$ and $c + di\nu$ commute;

3) if $\omega$ is any of $\beta, \gamma, \eta, \xi$ then $\omega i_{\nu+1} = i_{\nu+1} \overline{\omega}$;
c) \( p \) divides \( \alpha x \) if and only if \( p \) divides \( \beta \eta - \delta \xi \);

d) \( \alpha x \equiv 0 \pmod{p} \) has, modulo \( p \), exactly \( p^2 \) solutions in \( \mathbb{Z} \).

w) If \( p \) is an odd prime in \( \mathbb{Z} \) then, aside from associates, there are exactly \( p + 1 \) primes in \( \mathbb{Z} \) of norm \( p \).

7. (Jacobi's Theorem)

Let \( m \) be an odd number with the ordered factorization

\[ m = \frac{p_1 \cdots p_t p_1 \cdots p_2 \cdots p_t \cdots p_t}{\alpha_1 \alpha_2 \alpha_t}, \]

where \( p_1, \ldots, p_t \) are distinct primes in \( \mathbb{Z} \) and \( \alpha_1, \ldots, \alpha_t \) are positive integers. Then for each \( \alpha \) in \( \mathbb{Z} \) with \( N\alpha = m \) there is a prime factorization \( \alpha = \Pi_{i_1} \cdots \Pi_{i_{\alpha_t}} \cdots \Pi_{t_1} \cdots \Pi_{t_{\alpha_t}} \) such that \( N\Pi_{v_{\eta}} = p_{v_{\eta}} \) for \( 1 \leq v \leq t, 1 \leq \eta \leq \alpha_{v} \). Note that the primes \( \Pi_{v_{\eta}} \) may be in \( \mathbb{H} \setminus \mathbb{Z} \).
i) If for a given $\nu$ there is any $\eta$ such that $
pi_{\nu, \eta+1}$ and $
pi_{\nu, \eta}$ are associates then $\alpha$ is not primitive;

ii) If $\alpha$ is not primitive there exists a pair $\nu, \eta$ such that $\npi_{\nu, \eta+1}$ and $\npi_{\nu, \eta}$ are associates;

iii) the number of primitive $\alpha$ in $\mathcal{L}$ with $N\alpha = m$ is $8 \left( p_1 + 1 \right) p_1^{\alpha_1 - 1} \cdots \left( p_t + 1 \right) p_t^{\alpha_t - 1}$

$$= 8m \prod_{p \mid m} \left( 1 + \frac{1}{p} \right) ;$$

iv) the number of $\alpha$ in $\mathcal{L}$ with $N\alpha = m$ is $8 \sum m_p \frac{m_p}{\alpha_p} \prod_{p \mid m} \left( 1 + \frac{1}{p} \right) = 8 \sigma(m)$ ;

v) the number of $\alpha$ in $\mathcal{L}$ with $N\alpha = n$, $n$ an even integer in $\mathbb{Z}$, is $24\sigma^o(n)$, where $\sigma^o(n)$ is the sum of the odd divisors of $n$;

vi) (Jacobi's Theorem) the number of representations of a positive integer $n$ as a sum of 4 squares, representations which differ only in order or sign being counted as distinct, is $8$ times the sum of the divisors of $n$ which are not divisible by 4.
8. Write \( i = i_1, j = i_2, k = i_3 \) and put \( G_i = \{ a + i_1 b \mid a, b \in \mathbb{Z} \}, 1 \leq t \leq 3 \). Then \( G_t \subset H \) and, under the induced operations from \( H \), is a commutative subring of \( H \). It is easy to verify that \( G_1, G_2, G_3 \) are isomorphic. We write \( G \) for any of these and shall call the elements of \( G \) Gaussian integers. It is clear that if \( C \) is the set of all complex numbers one can write (where equality here indicates isomorphism) \( G = L \cap C \). Further, \( L = \{ \alpha + i_2 \beta \mid \alpha, \beta \in G_1 \} = \{ \alpha + i_3 \beta \mid \alpha, \beta \in G_2 \} = \{ \alpha + i_3 \beta \mid \alpha, \beta \in G_3 \} \).

If one replaces \( H \) by \( G \) in \#4-7 much of that theory carries over, in a simplified way (since we now have commutativity) to \( G \). Carrying out the details leads to the theorem:
if the canonical prime factorization of the rational integer \( n \) contains a 4k+3 prime to an odd power then \( n \) is not expressible as the sum of two rational integer squares; otherwise the number of representations as such a sum is \( 4(d_1(n) - d_3(n)) \), where \( d_j(n) \) is the number of odd divisors of \( n \) which are congruent to \( j \) modulo 4.

9. Let \( r_s(n) \) be the number of representations of \( n \) as a sum of \( s \) squares and define \( f_s(n) \) by \( f_s(n) = (2s)^{-1} r_s(n) \). Then

i) if \( n = ab \), \( (a, b) = 1 \), then

a) \( d_1(n) = d_1(a) d_1(b) + d_3(a) d_3(b) \);

b) \( d_3(n) = d_3(a) d_3(b) + d_1(a) d_1(b) \);

c) \( f_2 \) is multiplicative;

here \( d_1 \) and \( d_2 \) are as in \( \#8 \);
\[
\begin{align*}
\text{ii-a)} \quad r_4(n) &= \begin{cases} 
8 \sigma(n) & \text{for } n \text{ odd;} \\
24 \sigma^o(n) & \text{for } n \text{ even,}
\end{cases} \\
\text{where } \sigma^o(n) \text{ is the sum of the odd divisors of } n; \\
\text{b)} \quad f_4 \text{ is multiplicative;}
\end{align*}
\]

\[
\begin{align*}
\text{iii-a)} \quad r_5(2) &= 4 \left( \frac{5}{2} \right); \\
\text{b)} \quad r_5(3) &= 8 \left( \frac{5}{3} \right); \\
\text{c)} \quad r_5(6) &= 64 \left( \frac{5}{6} \right) + 24 \left( \frac{5}{3} \right); \\
\text{d)} \quad f_5(6) - f_5(2)f_5(3) &= \frac{2}{45} s(s-1)(s-2)(s-4)(s-8); \\
\text{e)} \quad \text{(Bateman [1969]) the only possible positive integers } s \text{ for which } f_s(n) \text{ is multiplicative are } 1, 2, 4, 8.
\end{align*}
\]

**Remarks.**

1. Clearly \( f_1 \) is multiplicative and in view of \( \text{ii-g} \) (i.e. \( \text{ii} \)) each of \( f_2, f_4 \) is multiplicative. Using the expression \( f_8(n) = (-1)^{n-1} 16 \sum_{d \mid n} (-1)^{d-1} d^3 \) (see Dickson's History II p. 315) it is easy to
see that $f_8$ is multiplicative. Thus $f_s$ is multiplicative precisely for $s = 1, 2, 4, 8$.

2. If $A$ is any associative algebra over a field $F$ with basis $e_1, \ldots, e_n$ one can define a function $N : A \to F$ by the equation

$$N(a_1 e_1 + \cdots + a_n e_n) = a_1^2 + \cdots + a_n^2.$$ 

When this function satisfies the equation $N(ab) = N(a)N(b)$ for all $a, b \in A$ one calls the algebra a normed algebra. If $A$ is a normed algebra with identity $1$ (we identify $a \in F$ with $a \cdot 1 \in A$) one may define a conjugate function $\bar{a}$ satisfying $\bar{\bar{a}} = a$, $\bar{ab} = \bar{b} \bar{a}$, $a \bar{a} = Na$ for all $a, b \in A$. Further, putting $Ta = a + \bar{a}$ we see that each $a \in A$ satisfies its monic second degree equation $x^2 - x \cdot Ta + Na = 0$. The real numbers, the complex numbers, and the real quaternions afford three examples of normed
algebras with identity over the reals. Suppose, now, $A$ is an arbitrary normed algebra with identity over the reals and suppose $\bar{a}$ is the conjugate of $a$ mentioned above. Put $B = A \times A$ and define multiplication in $B$ by $(a, b)(c, d) = (ac - \bar{a}b, da + b\bar{c})$. Identifying $1, j$ with $(1, 0), (0, 1)$ of $B$ each element $(a, b)$ of $B$ may be written $a + jb$. Putting $\bar{x} = \bar{a} - jb$ when $x = a + jb$ (the bar on the right of the expression for $\bar{x}$ is the conjugate in $A$) and defining $N x = x \bar{x}$ one can prove, when $A$ is associative, that $B$ is a normed algebra with identity over the reals. Starting with $A$ the real numbers, $B$ turns out to be the complex numbers. Taking $A$ to be the complex numbers, $B$ is the set of real quaternions. Finally, starting with $A$ as the real quaternions one obtains for $B$ the so-called
algebra of Cayley numbers. At this point, since the algebra of Cayley numbers is not associative, no new normed algebras over the reals arise. In fact, it can be shown that only the four normed algebras mentioned exist (see Curtis [1963]). Consideration of the norm function in the system of integral Cayley numbers leads to the 8 square theorem (see the Remarks in XI p. 86, Coxeter [1946], Curtis [1963], and Dickson [1927]). For the general arithmetic properties of quaternions, not only the above references but also Redei [1967], Dickson [1919, 1923], MacDuffee [1940], Hurwitz [1896, 1919] might be consulted. Finally we mention the paper by Vinogradov [1949] and the references therein.

3. An integer is a sum of 3 squares when it is not of the form \( 4^k(8t+7) \), 5 \( \geq \) 0, \( t \geq 0 \). For an elementary discussion see Weil [1974].
Brun's Theorem

Pairs of primes of the form \( p, p+2 \) are called twin primes. The number of primes \( p, p \leq x \), for which \( p+2 \) is prime is denoted by \( \Pi_2(x) \). It is not known if \( \Pi_2(x) \) increases without bound as \( x \) increases. Nevertheless, in 1919 Viggo Brun found an upper bound for \( \Pi_2(x) \) which, though increasing without bound as \( x \) increases, was sufficiently small to show that the sum \( \sum \frac{1}{p} \), taken over those primes \( p \) for which \( p+2 \) is prime, converges. In this chapter a proof of this result is given.

Throughout, \( x \) and \( z \) are positive real numbers with \( 2 < z < \sqrt{x} \), \( R \) is the product of the distinct primes not exceeding \( z \), \( a_n = n(n+2) \) for \( 1 \leq n \leq \lfloor x \rfloor \), and \( \nu(n) \) is the number of distinct prime divisors of \( n \).
1. Let $S = \sum_{n=1}^{[x]} 1$. Then $\Pi_2(x) \leq \pi + S$.

2. Let $S_\sigma$ be the number of $n, 1 \leq n \leq [x]$, for which $\sigma | a_n$ and suppose $2k \leq \nu(R)$. Then $S$, as in \#1, satisfies $S = \sum_{\sigma} (-1)^{\nu(\sigma)} S_\sigma$.

3. Putting $p(\sigma)$ for the number of $n$ in a complete system of residues mod $\sigma$ for which $\sigma | a_n$ then for $p$ any prime divisor of $R$ we have

$$p(p) = \begin{cases} 2 & \text{for } p \text{ odd;} \\ 1 & \text{for } p = 2, \end{cases}$$

and, therefore, for $\sigma$ any divisor of $R$

$$p(\sigma) = \begin{cases} 2^{\nu(\sigma)} & \text{for } \sigma \text{ odd;} \\ 2^{\nu(\sigma)-1} & \text{for } \sigma \text{ even.} \end{cases}$$

4. For each divisor $\sigma$ of $R$ there is a number $\Delta, |\Delta| \leq 1$, such that

$$S_\sigma = \left( \frac{x}{\sigma} + \Delta \right) p(\sigma),$$

where $S_\sigma, p(\sigma)$ are as in \#2, \#3.
5. The $S$ of $n_1$ and $n_2$ satisfies the inequality

$$S \leq x(T_1 + T_2) + T_3,$$

where

a) $$T_1 = \sum_{\delta \in \mathbb{R}} (-1)^{\nu(\delta)} \frac{\rho(\delta)}{\delta} = \frac{1}{2} \sum_{2 < p \leq x} (1 - \frac{2}{p}) ;$$

b) $$T_2 = \sum_{\delta \in \mathbb{R}, \nu(\delta) > 2k} \frac{\rho(\delta)}{\delta} \leq \sum_{j \geq k+1} \frac{1}{j} \sum_{\nu(\delta) = j} \frac{1}{\delta} ;$$

c) $$T_3 = \sum_{\delta \in \mathbb{R}, \nu(\delta) \leq 2k} \rho(\delta) \leq \sum_{j = 0}^{2k} \left( \prod_{j} \phi(j) \right) 2^{-j} .$$

6. It is possible to choose a positive constant $A$ so that $eA \ln 2 > 1$ and $\sum_{p \leq x} \frac{1}{p} < A \ln \ln t$, for all $t$.

7. Taking $A$ as in #6 and putting $z = x^\alpha$, $\alpha = (6eA \ln \ln x)^{-1}$, there is an $x_0$ such that for $x \geq x_0$

$$2 [2eA \ln \ln z] + 2 < \Pi(z) ;$$

$$\frac{\ln x}{\ln \ln x} > 24eA ;$$

$$\frac{1}{eA \ln \ln x} < \frac{1}{3} .$$
8. For \( A \) as in \( \#6 \) and \( z, x_0 \) as in \( \#7 \) and with
\[
k = \left\lfloor 2eA \ln \ln 3 \right\rfloor + 1
\]
we have, for \( x \geq x_0, \ 2 \leq z < \sqrt{x} \) and \( 2k < \sqrt{\nu(R)} \).

9. Let \( A, z, x_0, k \) be as in \( \#6-8 \); then for \( x \geq x_0 \)
and all sufficiently large positive constants \( B \) we have:

\[a) \quad T_1 \leq \frac{1}{2} \prod_{p \leq R} \left( 1 - \frac{1}{p} \right)^2 \leq \frac{1}{2} \left( \prod_{p \leq R} \left( 1 - \frac{1}{p} \right)^{-1} \right)^2 \]

\[< \frac{1}{2} \left( \frac{2}{\ln 3} \right)^2 < \frac{B}{(\ln 3)^2} ; \]

\[b) \quad T_2 \leq \sum_{j=2k+1}^{\infty} \left( \sum_{p \leq 3} \frac{1}{p} \right)^j \frac{2^j}{j!} \leq \sum_{j=2k+1}^{\infty} \left( \frac{2eA\ln \ln 3}{j} \right)^j \]

\[< 2^{-2k} < \frac{1}{(\ln 3)^2} ; \]

\[c) \quad T_3 \leq (\pi(3z))^{2k} \sum_{j=0}^{2k} \frac{z^j}{j!} < C^2 (\pi(3z))^{2k} < 9z^{2k} . \]

10. For a suitable positive constant \( C \) and
all sufficiently large \( x \) we have
\[
\pi_2(x) < C x \left( \frac{\ln \ln x}{\ln x} \right)^2 .
\]
11. (Brun 1919)

a) \( \sum \frac{1}{p} \), where the sum is over all primes \( p \) such that \( p+2 \) is a prime, converges.

b) \( \sum \frac{1}{p} \), where the sum is over all primes occurring in a twin prime pair, converges.

Remarks.

1. The theorem of this chapter was first proved by Brun [1919]. Expositions will be found in Gelfond, Linnik [1965], Rademacher [1964], Landau [1958]. Extensions of the method of Brun may be found in Trost [1967], Prachar [1957], and Halberstam, Roth [1966].

2. The conjecture that \( \pi_2(x) \) tends to infinity with \( x \) is called the twin prime conjecture.
This is the special case \( k = 2, b_1 = 0, b_2 = 2 \) of the conjecture: if \( b_1, \ldots, b_k \) are non-negative integers such that for each prime \( p \) there is an integer
n with $6_n+n, \ldots, 6_n+n$ all non-divisible by $p$ then for infinitely many values of $n$ the latter $k$ numbers are all prime. Though this conjecture has not been proved Richards [1974] has shown that it is not compatible with the following conjecture made by Hardy and Littlewood in 1923: $\pi(x+y) \leq \pi(x) + \pi(y)$ for $x, y$ integers $\geq 2$.

An even more general conjecture, of which the twin prime conjecture is a very special case, goes under the name of hypothesis $\mathcal{H}$. For details see Sierpinski [1964 a] p 127 ff.
xvii Quadratic Residues

1. i) Suppose \( a > 0, D = b^2 - 4ac \), \( f(x) = ax^2 + bx + c \). Then \( f(x) \equiv 0 \pmod{m} \) if and only if
   \[(2ax + b)^2 \equiv D \pmod{4am};\]

ii) when \( (a, m) = d = td^2 \) where \( t \) is the square free part of \( d \), then the following two statements are equivalent:
   a) \( x^2 \equiv a \pmod{m} \) is solvable;
   b) \( (t, \frac{m}{d}) = 1 \) and \( x^2 \equiv \frac{ta}{d} \pmod{\frac{m}{d}} \) is solvable.

(Thus, solvability of a general quadratic congruence is reducible to that of a pure quadratic congruence of the form \( x^2 \equiv a \pmod{m} \) which, in turn, may be reduced to a similar congruence in which \( (a, m) = 1 \).)

Definition: \( n \) is a quadratic residue (qr) of, or modulo, \( m \) if \( x^2 \equiv n \pmod{m} \) is solvable; otherwise, \( n \) is a quadratic non-residue (qnr) of, or modulo, \( m \).
In the following whenever we speak about quadratic residues we exclude 0.

2. i) \( x^2 \equiv 12 \pmod{45} \) is not solvable; i.e. 12 is a qnr of 45;
   ii) \( x^2 \equiv 252 \pmod{1575} \) is solvable if and only if \( x^2 \equiv 3 \pmod{25} \) is solvable; i.e. 252 is a qr of 1575 if and only if 3 is a qr of 25.

3. In this problem all congruences \( x^2 \equiv a \pmod{m} \) are to satisfy \((a, m) = 1\). This congruence, where \( m = p^\alpha \), with \( p \) a prime will be denoted by \((\ast_\alpha)\). Thus

\[(\ast_\alpha) \quad x^2 \equiv a \pmod{p^\alpha}, \ (a, p) = 1, \ p \text{ prime.}\]

i) If \( p = 2 \) then
   a) \((\ast_1)\) is solvable and has 1 solution;
   b) \((\ast_2)\) is solvable if and only if \( a \equiv 1 \pmod{4} \);
   c) \((\ast_2)\), when solvable, has exactly 2 solutions;
d) \((*_{3})\) is solvable if and only if \(a \equiv 1 \pmod{8}\);
e) if \(\alpha \geq 3\) then \((*_{\alpha+1})\) is solvable if and only if \((*_{\alpha})\) is solvable;
f) for \(\alpha \geq 3\), \((*_{\alpha})\), when solvable, has exactly 4 solutions;
g) the number of solutions of \((*_{\alpha})\), \(\alpha \geq 1\), is:
\[
\begin{cases}
1 & \text{for } \alpha = 1, \text{ } a \text{ odd}; \\
2 & \text{for } \alpha = 2, \text{ } a \equiv 1 \pmod{4}; \\
4 & \text{for } \alpha \geq 3, \text{ } a \equiv 1 \pmod{8}; \\
0 & \text{otherwise}.
\end{cases}
\]
i) if \(p > 2\) then
   a) \((*_{1})\) has 0 or 2 solutions;
   b) if \(x_{0}\) is a solution of \((*_{\alpha})\) then there is a unique \(t\), \(0 \leq t < p\), such that \(x_{0} + tp^{\alpha}\) is a solution of \((*_{\alpha+1})\);
   c) \((*_{\alpha+1})\) is solvable if and only if \((*_{\alpha})\) is solvable;
   d) \((*_{\alpha})\), when solvable, has exactly 2 solutions;
(Helping lemma from the theory of congruences)

let \( f \) be an integral polynomial and suppose \( m_1, \ldots, m_r \) are pairwise relatively prime; let \( N_j \), \( 1 \leq j \leq r \), be the number, modulo \( m_j \), of solutions of \( f(x) \equiv 0 \pmod{m_j} \) and let \( N \) be the number, modulo \( m_1 \cdots m_r \), of solutions of the system

\[
\begin{align*}
 f(x) & \equiv 0 \pmod{m_1}, \ldots, f(x) & \equiv 0 \pmod{m_r}; \\
\text{then } N & = N_1 \cdots N_r;
\end{align*}
\]

iv) a) \( a \) is a q.r. of \( m \) if and only if

\( a \) is a q.r. of every prime divisor of \( m \);

\( a \equiv 1 \pmod{4} \) when \( 4 \mid m \) and \( 8 \nmid m \);

\( a \equiv 1 \pmod{8} \) when \( 8 \mid m \);

b) when \( a \) is a q.r. of \( m \) the number of solutions of \( x^2 \equiv a \pmod{m} \) is:

\[
\begin{cases}
2^k & \text{if } 4 \nmid m; \\
2^{k+1} & \text{if } 4 \mid m \text{ and } 8 \nmid m; \\
2^{k+2} & \text{if } 8 \mid m,
\end{cases}
\]

where \( k \) is the number of distinct odd prime factors of \( m \).
(Thus, solvability of general quadratic congruences reduces to solvability of quadratic congruences of the form \( x^2 \equiv a \pmod{p} \), where \( p \) is an odd prime not dividing \( a \).)

4. Let \( p \) be an odd prime and suppose \( p \) does not divide \( a \). Then:

i) exactly one of the following congruences is valid: \( a^{\frac{p-1}{2}} \equiv 1 \pmod{p} \), \( a^{\frac{p-1}{2}} \equiv -1 \pmod{p} \);

ii) if \( a \) is a QR of \( p \) then \( a^{\frac{p-1}{2}} \equiv 1 \pmod{p} \);

iii-a) \( x^{p-1} - 1 = (x^2 - a)q(x^2) + a^{\frac{p-1}{2}} - 1 \), where \( q \) is a polynomial of degree \( \frac{p-3}{2} \);

b) if \( a^{\frac{p-1}{2}} \equiv 1 \pmod{p} \) then \((x^2 - a)q(x^2) \equiv 0 \pmod{p}\) is satisfied for all \( x \) not divisible by \( p \);

iv) (Euler’s criterion)

- \( a \) is a QR of \( p \) if and only if \( a^{\frac{p-1}{2}} \equiv 1 \pmod{p} \);
- \( a \) is a QNR of \( p \) if and only if \( a^{\frac{p-1}{2}} \equiv -1 \pmod{p} \).
Definition: For \( p \) an odd prime not dividing \( a \) we write \( \left( \frac{a}{p} \right) = \begin{cases} 1 & \text{if } a \text{ is a } qf \text{ of } p; \\ -1 & \text{if } a \text{ is a qnr of } p. \end{cases} \)

This symbol \( \left( \frac{a}{p} \right) \) is called the Legendre symbol.

5. Let \( p \) be an odd prime not dividing \( ab \). Then:

i) \( \left( \frac{a^2}{p} \right) = 1; \)

ii) \( \left( \frac{a}{p} \right) \equiv a^{\frac{p-1}{2}} \pmod{p} \) (this is also called Euler's criterion);

iii) if \( a \equiv b \pmod{p} \) then \( \left( \frac{b}{p} \right) = \left( \frac{a}{p} \right) \);

iv) if \( p \nmid ab \) then \( \left( \frac{ab}{p} \right) = \left( \frac{a}{p} \right) \left( \frac{b}{p} \right) \);

v) a) if \( 0 < a < b \leq \frac{p-1}{2} \) then \( a^2 \not\equiv b^2 \pmod{p} \);

b) if \( 0 < a \leq p-1 \) then there is a \( b \), \( 0 < b < \frac{p-1}{2} \) such that \( a^2 \equiv b^2 \pmod{p} \);

c) if \( \left( \frac{a}{p} \right) = 1 \) then \( a \equiv b^2 \pmod{p} \) for some \( b \), \( 0 < b \leq \frac{p-1}{2} \);

vi) \( \left( \frac{-1}{p} \right) = (-1)^{\frac{p-1}{2}} \).
(Referring to the result in (vi) Gauss wrote in the introduction to his monumental *Disquisitiones Arithmeticae* the following: “Engaged in other work I chanced upon an extraordinary arithmetic truth …. Since I considered it to be so beautiful in itself and since I suspected its connection with even more profound results, I concentrated on it all my efforts in order to understand the principles on which it depended and to obtain a rigorous proof.”)

6. i) Every square is a qr of \( p \);

ii) numbers congruent modulo \( p \) are either both qr or both qnr of \( p \);

iii) the product of two numbers with the same quadratic character modulo \( p \) is a qr of \( p \), while the product of two numbers with different quadratic character modulo \( p \) is a qnr of \( p \);
w) half of the numbers 1, 2, ..., p - 1 are qr and half are qnr of p.

7. Let p be an odd prime.
   i) if \((\frac{n}{p}) = -1\) then \(\sum_{d|n} d^{\frac{p-1}{2}} \equiv 0 \pmod{p}\);
   ii) \(\sum_{k=1}^{p-1} (\frac{k}{p}) = 0\);
   iii-a) at least one of \(a, b, ab\) is a qr of \(p\) when \(p \nmid ab\);
   b) every prime divides at least one value of \(x^6 - 11x^4 + 36x^2 - 36\);
   iv) if \((ax_o, by_o) = 1\) then \(ax_o^2 + by_o^2 \equiv 0 \pmod{p}\) implies \((a) = (b)\).

8. Let p be an odd prime. Then:
   i) \(\prod_{(\frac{a}{p}) = 1} a \equiv -1 \pmod{p}\) and \(\prod_{(\frac{a}{p}) = -1} a \equiv 1 \pmod{p}\);
   ii) if \(a_1, \ldots, a_s\) are the qr of \(p\) among \(1, 2, \ldots, \frac{p-1}{2}\) then
      a) if \(p \equiv 1 \pmod{4}\) then \(p - a, \ldots, p - a_s\) are the qr of \(p\) among \(\frac{p+1}{2}, \ldots, p - 1\);
6) If $p \equiv 3 \pmod{4}$ then $p - a_1, \ldots, p - a_s$ are the qnr of $p$ among $\frac{p+1}{2}, \ldots, p-1$;

c) If $p \equiv 1 \pmod{4}$ then the qr of $p$ are symmetrically distributed about $\frac{p}{2}$;

d) $(-1)^{s+1} \equiv \begin{cases} 
(a_1 \cdots a_s)^2 \pmod{p} & \text{if } p \equiv 1 \pmod{4}; \\
\left(\frac{p-1}{2}\right)! \pmod{p} & \text{if } p \equiv 3 \pmod{4}.
\end{cases}$

9. The mod $p$ residues of $a, 2a, \ldots, \frac{p-1}{2}a$ which lie between $-\frac{p}{2}$ and $\frac{p}{2}$ will be denoted by $a_1, \ldots, a_{\frac{p-1}{2}}$. Again $p$ is an odd prime and we assume $p$ does not divide $a$. Then:

i) the $|a_j|$, $1 \leq j \leq \frac{p-1}{2}$, are pairwise unequal;

ii) if $v$ is the number of $a_1, \ldots, a_{\frac{p-1}{2}}$ which are negative then

$$(-1)^v\left(\frac{p-1}{2}\right)! = a_1 \cdots a_{\frac{p-1}{2}} \equiv a_{\frac{p-1}{2}} \left(\frac{p-1}{2}\right)! \pmod{p};$$

iii) (Lemma of Gauss)

$$\left(\frac{a}{p}\right) = (-1)^v,$$ where $v$ is as in (ii).
In problems *10-13* the V is always that introduced in *9(*\(\tilde{w}\))*.

10. Let \(p\) be an odd prime and suppose \(a = 2\).

Then:

1) \(V\) is the number of \(j\), \(1 \leq j \leq \frac{p-1}{2}\), for which \(\frac{p}{2} < 2j < p\);

2) \(V = \left[\frac{p}{2}\right] - \left[\frac{p}{4}\right] \equiv \begin{cases} 0 \mod 2 & \text{if } p \equiv \pm 1 \mod 8; \\ 1 \mod 2 & \text{if } p \equiv \pm 3 \mod 8; \end{cases}\)

3) \(\left(\frac{3}{p}\right) = (-1)^{\frac{p^2-1}{8}};\)

4) \(2\) is a qr of all \(8k+1\) primes and a qnr of all \(8k+3\) primes.

(Fermat claimed to have a proof of *10(\(\tilde{w}\)) but did not publish it. Euler tried to prove it but without success. Lagrange gave the first correct proof in 1775.)

11. Let \(p\) be an odd prime other than 3 and suppose \(a = 3\). Then:
1) \( V \) is the number of \( j \), \( 1 \leq j \leq \frac{p-1}{2} \), for which \( \frac{p}{2} < 3j < p \); 

2) \( V = \left[ \frac{p}{3} \right] - \left[ \frac{p}{6} \right] \equiv \begin{cases} 0 \pmod{2} & \text{if } p \equiv \pm 1 \pmod{12} ; \\ 1 \pmod{2} & \text{if } p \equiv \pm 5 \pmod{12} ; \end{cases} \)

3) \( 3 \) is a QR of all \( 12k \pm 1 \) primes and a QNR of all \( 12k \pm 5 \) primes.

(Fermat knew these results but they were first proved by Euler. It is interesting to note, as does Gauss in his Disquisitiones Arithmeticae, that even after Euler proved \#11(iii) he was unable to prove \#10(iv).)

12. Let \( p \) be an odd prime other than 5 and suppose \( a = 5 \). Then:

1) \( V \) is the number of \( j \), \( 1 \leq j \leq \frac{p-1}{2} \), for which \( \frac{p}{2} < 5j < p \) or \( \frac{3p}{2} < 5j < 2p \);

2) \( V = \left[ \frac{p}{5} \right] - \left[ \frac{p}{10} \right] + \left[ \frac{2p}{5} \right] - \left[ \frac{3p}{10} \right] \);

3) \( 5 \) is a QR of all \( 20k \pm 1 \) and \( 20k \pm 9 \) primes and is a QNR of all \( 20k \pm 3 \) and \( 20k \pm 7 \) primes.
13. (The Quadratic Reciprocity Law)

Let $p$ and $q$ be different odd primes. Then:

(i) if $p \equiv \pm q \pmod{4a}$ then $(\frac{a}{p}) = (\frac{a}{q})$;

(ii) there is an $a$ such that $(a, pq) = 1$ and $p = \pm q + 4a$;

(iii) $(\frac{p}{q}) = \bigg\{ \begin{array}{ll}
(\frac{-q}{p}) & \text{if } p \equiv q \pmod{4}; \\
(\frac{q}{p}) & \text{if } p \not\equiv q \pmod{4};
\end{array}$

(iv) (the reciprocity law)

$$(\frac{p}{q})(\frac{q}{p}) = (-1)^{\frac{p-1}{2} \cdot \frac{q-1}{2}}.$$  

(Bachmann in his Niedere Zahlentheorie (v. 1 p. 202) calls this theorem one of the most beautiful and important in all of number theory. Euler discovered the law by induction in 1738. Legendre invented his symbol in 1785 and stated the law in the form given in #13 (iv). Gauss discovered the law independently in 1795. He claimed that his first proof, which was the first known, eluded his most strenuous efforts for more than a year. Altogether Gauss gave
8 proofs of the law before he died. Bachmann catalogues over 45 proofs as of 1901 and there have been many more discovered since that time. In the 2nd volume of Gauss' collected works one finds a table, computed by Gauss, listing the values of \( (\frac{p}{q}) \) for \( 2 \leq p \leq 997, 3 \leq q \leq 503 \).

14. Consider the pair of congruences
\[ x^2 \equiv p \pmod{q}, \quad x^2 \equiv q \pmod{p}, \]
where \( p \) and \( q \) are odd primes. If at least one of \( p \) and \( q \) is a \( 4k+1 \) prime then the two congruences are either both solvable or both not solvable while if both \( p \) and \( q \) are \( 4k+3 \) primes then exactly one of the congruences is solvable.

Definition (The Jacobi Symbol): Let \( m = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \) be a positive odd integer. For \( (n,m) = 1 \) put
\[ (\frac{n}{m}) = (\frac{n}{p_1})^{\alpha_1} \cdots (\frac{n}{p_k})^{\alpha_k}. \]
This symbol \( (\frac{n}{m}) \) is called the Jacobi symbol.
15. Let \( m \) and \( n \) be odd positive integers and suppose \((a, m) = (b, m) = 1\). Then:

i) for \( m \) a prime the Jacobi symbol \((\frac{a}{m})\) is the Legendre symbol \((\frac{a}{m})\);

ii) \((\frac{1}{m}) = 1 = (\frac{a^2}{m})\);

iii) if \( a \) is a qr of \( m \) then \((\frac{a}{m}) = 1\);

iv) \((\frac{a}{m})\) may equal 1 without \( a \) being a qr of \( m \);

v) if \( a \equiv b \pmod{m} \) then \((\frac{a}{m}) = (\frac{b}{m})\);

vi) \((\frac{a}{mn}) = (\frac{a}{m})(\frac{a}{n})\);

vii) \((\frac{ab}{m}) = (\frac{a}{m})(\frac{b}{m})\);

viii) \((\frac{-1}{m}) = (-1)^{m-1 \over 2}\);

ix) \((\frac{2}{m}) = (-1)^{m^2 - 1 \over 8}\);

x) \((\frac{n}{m})(\frac{m}{n}) = (-1)^{n-1 \over 2} \cdot m^{-1} \cdot m^{-1}\).

16. i) Calculate

a) \((\frac{89}{197})\); b) \((\frac{1050}{1573})\); c) \((\frac{12345}{6789})\);

ii) which of the following congruences are solvable;

a) \(x^2 \equiv 89 \pmod{197}\); b) \(x^2 \equiv 197 \pmod{89}\);

c) \(x^2 \equiv 1050 \pmod{1573}\); d) \(x^2 \equiv 1573 \pmod{1050}\);

e) \(x^2 \equiv 111 \pmod{219}\); f) \(x^2 \equiv 219 \pmod{111}\).
17. Let \( f(x) = x^2 + x + 41 \). Then:

i) no prime \( < 41 \) divides any value of \( f(x) \);

ii) all values of \( f(x) \) in absolute value \( < 41^2 \)
are prime;

iii) \( f(x) \) is prime for 80 consecutive integers.
(The polynomial in \#17 represents a prime 4506 times in the first 11000 values of \( x \). It was discovered in 1772 by Euler. A somewhat "better" prime representing polynomial is \( x^2 + x + 72491 \) which represents a prime 4923 times in the first 11000 values of \( x \). See Beefer [1939], Szekeres [1974].)

18. (Theorem of Zolotareff)

Let \( p \) be an odd prime and suppose \( A \) is a reduced residue system modulo \( p \). For each integer \( a \) not divisible by \( p \) there is a modulo \( p \) reciprocal \( a^{-1} \) and an element \( \tilde{a} \) in \( A \) congruent to \( a \).

Thus

\[ a a^{-1} \equiv 1 \pmod{p}, \quad a \equiv \tilde{a} \pmod{p}, \quad \tilde{a} \in A. \]
For each integer $D$ not divisible by $p$ we define mappings $Z_0, T_0$ of $A$ into $A$ by
\[ Z_0 a = D a \quad , \quad T_0 a = D a^{-1} \]

i) $Z_0, T_0$ are permutations;

ii) $T_0$ is an involution; i.e. $T_0^{-1} = T_0$;

iii) $Z_0 = T_0 T_1$;

iv) if $\alpha_D$ is the number of elements kept fixed by $T_0$ then
\[ \alpha_D = \begin{cases} 2 & \text{if } D \text{ is a qr of } p ; \\ 0 & \text{otherwise} ; \end{cases} \]

v) defining the signature of a permutation $\pi$, sgn $\pi$, to be 1 or -1 depending on whether the permutation is even or odd we see that
\[ \text{sgn } T_0 = (-1)^{\frac{\varphi(p) - \alpha_0}{2}}, \quad \text{sgn } Z_0 = (-1)^{\frac{\alpha_0 + \alpha_1}{2}} ; \]

vi) $\alpha_1 = 2$;

vii) $\text{sgn } Z_0 = \left( \frac{D}{p} \right) ;$
viii) (Theorem of Zolotareff) 

\( D \) is a QR of \( p \) if and only if the least positive residues of \( D, 2D, \ldots, (p-1)D \) constitute an even permutation of \( 1, 2, \ldots, p-1 \);

ix) noting that \( A \) can be any reduced system of residues modulo \( p \) we can use the above to give independent evaluations of \( (\frac{-1}{p}) \) and \( (\frac{3}{p}) \).

19. (Quadratic reciprocity theorem from Zolotareff's theorem) Let \( \mathcal{A}^+ = \{1, 2, \ldots, \frac{p-1}{2}\} \), \( \mathcal{A}^- = \{-\frac{p-1}{2}, \ldots, -1\} \), and put \( \mathcal{A} = \mathcal{A}^- \cup \mathcal{A}^+ \). Define \( \mathcal{Z}_0 \) as in §18 and call \( a', a'' \) an inversion if \( a' < a'' \) and \( \mathcal{Z}_0 a' > \mathcal{Z}_0 a'' \). Then:

i) If \( a', a'' \) is an inversion so also is \(-a'', -a'\);

ii) Inversions occur in pairs except for those of the form \(-a, a\);

iii) (Lemma of Gauss) \( \text{sgn} \mathcal{Z}_0 = (-1)^N \), where \( N \) is the number of elements in \( \{D, 2D, \ldots, \frac{p-1}{2}D\} \) with least absolute remainders, modulo \( p \), in \( \mathcal{A}^- \);
iv) if \( N \) is the number of elements in 
\( \{ q, 2q, \ldots, \frac{p-1}{2}q \} \) with negative least absolute residues modulo \( p \) and \( v \) is the number of elements in \( \{ p, 2p, \ldots, \frac{q^{-1}}{2}p \} \) with negative least absolute residues modulo \( q \), \( q \) an odd prime distinct from \( p \), then

\[
\left( \frac{p}{q} \right) \left( \frac{q}{p} \right) = (-1)^{N+v} ;
\]

v) let \( x, y \) satisfy \( 1 \leq x \leq \frac{p-1}{2}, 1 \leq y \leq \frac{q^{-1}}{2} \); then each pair \( x, y \) leads to exactly one of the following four inequalities

\[
q x - py < -\frac{p}{2}
\]

\[
-\frac{p}{2} < q x - py < 0
\]

\[
0 < q x - py < \frac{q}{2}
\]

\[
\frac{q}{2} < q x - py
\]

vi) the number of pairs \( x, y \) in (v) leading to the first of the inequalities is the same as the number leading to the last of the inequalities and the number of pairs satisfying the second (third) inequalities is just \( N \) (v) ;
vii) (the Quadratic reciprocity law)
\[ \left( \frac{p}{q} \right) \left( \frac{q}{p} \right) = (-1)^{p-1 \cdot q-1} \cdot p^2 \cdot q^2. \]

(The theorem of Zolotareff given in *18 was first proved by Zolotareff [1872]. In our discussion in *18, *19 we have followed Riesz [1953], Cartier [1970], and Frobenius [1914] (see Gesammelte Abh. 1968 pp 628-649). For other recent treatments of Zolotareff's theorem along other lines see Rademacher, Grosswald [1972], Brenner [1973], and Roberts [1969].)
Exponents, Primitive Roots, 
P\sim \text{ Power Residues}

When a and m are relatively prime positive integers, Euler's theorem assures us of the existence of positive integers t for which 
\[ a^t \equiv 1 \pmod{m} \]. The smallest such t is called the exponent of a mod m and will be denoted by \( P_m(a) \) (or just \( P(a) \) when the modulus is understood). The number of mod m solutions of \( P_m(x) = t \) is denoted by \( \Psi_m(t) \) (or just \( \Psi(t) \)). If \( P_m(a) = \Psi(m) \), one says that a is a primitive root of m. As we shall see, not all m have primitive roots. Throughout we assume \((a,m) = 1\).

1. In this problem \( P(a) \) and \( \Psi(t) \) are used for \( P_m(a) \), \( \Psi_m(t) \). Then:
   i) \[ a^s \equiv a^t \pmod{m} \] if and only if 
   \[ s \equiv t \pmod{P(a)} \];
ii) from (i):
   a) \(a^s \equiv 1 \pmod{m}\) if and only if \(s \equiv 0 \pmod{\varphi(a)}\);
   b) \(\varphi(a) \mid \varphi(m)\);
   c) \(a, a^2, \ldots, a^{\varphi(a)}\) are incongruent, modulo \(m\), solutions of \(x^{\varphi(a)} \equiv 1 \pmod{m}\);

iii) \(\varphi(a^k) = \frac{\varphi(a)}{(k, \varphi(a))}\);

\(\psi\)-a) \(\psi(t) = 0\) when \(t \nmid \varphi(m)\);
   b) \(\sum_{t \mid \varphi(m)} \psi(t) = \varphi(m)\);
   c) if \(\psi(t) \neq 0\) then \(\varphi(t) \leq \psi(t)\);

v) if \(m = p, p\) a prime, then
   a) if \(\psi_p(t) \neq 0\) then \(\varphi(t) = \psi(t)\);
   b) \(\psi_p(t) = \varphi(t)\) for all \(t\) such that \(t \mid p-1\);

vi) every prime \(p\) has exactly \(\varphi(p-1)\) primitive roots.

2. Let \(p\) be an odd prime and \(\alpha\) be a positive integer. Then:

   i) if \(g\) is a primitive root of \(p\) and if \(g^{\varphi(p^\alpha)} \not\equiv 1 \pmod{p^\alpha}\) then \(g\) is a primitive root of \(p^\alpha\);
ii) If \( g \) is a primitive root of \( p \) then one of \( g, g+p \) is a primitive root of \( p^2 \);
iii) Every primitive root of \( p^2 \) is also a primitive root of \( p^\alpha \) for \( \alpha > 2 \);
iv) If \( g \) is a primitive root of \( p^\alpha \) the odd one of \( g, g+p^\alpha \) is a primitive root of \( 2p^\alpha \) while the even one is not;
v) Every number of the form \( p^\alpha \) or \( 2p^\alpha \) has a primitive root (recall that \( p \) here is odd);
vii) Only 2, 4 and the numbers specified in (v) have primitive roots.

3. Let \( p \) be an odd prime. Then:

i) Every primitive root of any positive integral power of \( p \) is a primitive root of all smaller positive integral powers of \( p \);
ii) When \( g \) is a primitive root of \( p \) the numbers \( (1+sp)g, 0 \leq s < p \), with one exception, are primitive roots of \( p^2 \);
iii) every primitive root of $p$ is congruent modulo $p$ to exactly $p-1$ primitive roots of $p^2$ and, consequently, there are exactly $\varphi(\varphi(p^2))$ primitive roots of $p^2$;

iv) every primitive root of $p^\alpha$, $\alpha \geq 2$, is congruent modulo $p^\alpha$ to exactly $p$ primitive roots of $p^{\alpha+1}$;

v) there are exactly $\varphi(\varphi(p^\alpha))$ primitive roots of $p^\alpha$;

vi) if $m$ has a primitive root it has exactly $\varphi(\varphi(m))$ of them.

(In the above we have proved:
the only integers having primitive roots are 2, 4, powers of odd primes, and twice such powers; when $m$ has a primitive root it has, modulo $m$, exactly $\varphi(\varphi(m))$ of them.)
4. In this problem we discuss the exponent function in a little greater detail and the results lead to another proof that every prime has exactly \( \Phi(p-1) \) primitive roots. The only earlier results we use are \#1 (i - iii). Throughout we use \( P(a) \) for \( P_m(a) \).

i) If \( P(a) = uv \) then \( P(a^u) = v \);

ii) If \( (P(a), P(b)) = 1 \) then \( P(ab) = P(a)P(b) \);

iii) It is false that \( P(ab) \) is the least common multiple of \( P(a) \) and \( P(b) \) in all instances;

iv) For given \( a, b \) there is a \( c \) such that \( P(c) \) is the largest common multiple of \( P(a) \) and \( P(b) \);

v) All exponents modulo a given \( m \) divide the largest exponent;

vi) Every prime has a primitive root;

vii) Every prime \( p \) has \( \Phi(p-1) \) primitive roots.
5. Some of the ideas in *4 are useful in the study of Abelian groups. We illustrate this here. Once more the results lead to a proof of *1 (vi). We let $G$ be an Abelian group and write $A_G$ for the set of positive integers which are orders of elements of $G$. Then:

i) if $u, v$ are in $A_G$ then $[u, v] \in A_G$;

ii) if $A_G$ has a largest element $P$ then all elements of $A_G$ divide $P$;

iii) every finite subgroup of the multiplicative group of a field is cyclic;

iv) the multiplicative group of a finite field is cyclic;

v) every prime has $\varphi(p-1)$ primitive roots.

Definition: If $p$ is a prime and $x^n \equiv a \pmod{p}$ is solvable we call $a$ an $n$th power residue modulo $p$. 
6. Let \( a \) be an integer not divisible by the prime \( p \) and suppose \((n, p-1) = d\). Then:

i) \( a \) is an \( n^{th} \) power residue modulo \( p \) if and only if \( a^{\frac{p-1}{d}} \equiv 1 \pmod{p} \);

ii) let \( \delta \) be a divisor of \( p-1 \); then \( a \) is a \( \delta^{th} \) power residue modulo \( p \) if and only if \( a^{\frac{p-1}{\delta}} \equiv 1 \pmod{p} \);

iii) if \( \delta \mid p-1, \delta > 1 \), then there is an integer which is not a \( \delta^{th} \) power residue modulo \( p \);

iv) if \( p-1 = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \) and \( A_i, 1 \leq i \leq k \), is not a \( p_i^{th} \) power residue modulo \( p \) and \( B_i = A_i^{\frac{p-1}{p_i^{\alpha_i}}}, 1 \leq i \leq k \), then

a) the exponent of \( B_i \) modulo \( p \) is \( p_i^{\alpha_i} \);

b) \( B_1 \cdots B_k \) is a primitive root modulo \( p \).

7. i) Using *6 it is easy to find a primitive root modulo 43;

ii) using the primitive root found in (i) enables us to construct a table of exponents
modulo 43 and use it to find all primitive roots, the least positive primitive root, and the primitive root with least absolute value.

8. In the following, in each instance, "all integers" refers to all integers not divisible by the primes in question.

i) All integers are cubic residues modulo 5 and 11;

ii) all integers are quintic residues modulo 7;

iii) all integers are \( n^{16} \) power residues, for all odd \( n \), modulo 5 and 17;

iv) a necessary and sufficient condition that all integers are \( n^{16} \) power residues modulo an odd prime \( p \), for all odd \( n \), is that \( p \) be a Fermat prime;

v) if \( n \) is a fixed odd integer there are infinitely many primes for which not all integers are \( n^{16} \) power residues.
9. For $p$ a prime

$$1^n + 2^n + \cdots + (p-1)^n \equiv \begin{cases} 0 \mod p & \text{if } p-1 \nmid n; \\ -1 \mod p & \text{if } p-1 \mid n. \end{cases}$$

10. When $a$ and $n$ are positive integers, $n$ divides $\varphi(a^n - 1)$.

11. The product of all primitive roots of an odd prime $p$ is congruent to 1 modulo $p$.

12. The following generalization of Wilson's theorem is true.

$$\prod_{n=1}^{\varphi(m)} n \equiv \begin{cases} -1 \mod m & \text{if } m \text{ has a primitive root}; \\ 1 \mod m & \text{otherwise}. \end{cases}$$

13. (L. Marx)

The arithmetic progression $(x > 0)$

$$x, 3x+1, 5x+2, 7x+3, \ldots$$

always contains a power of 2 or a number 1 smaller than a power of 2; i.e. it always
contains a term of the form \( 2^a \) or \( 2^a - 1 \) \((Q \geq 0)\); further, the smallest such \( a \) is \( x \) and, if \( t \) is the exponent of 2 modulo \( 2x+1 \), is given by

\[
Q = \begin{cases} 
\frac{1}{2}t-1 & \text{when } t \text{ is even and } 2^{\frac{t}{2}} \equiv -1 \pmod{2x+1}; \\
\quad t-1 & \text{otherwise.}
\end{cases}
\]

14. The sequence 5, 12, 19, 26, 33, 40, 47, \ldots contains no term of the form \( 2^a \) or \( 2^a - 1 \).

15. i) For each positive integer \( n \)

\[
5^{2^n} - 1 = 4 \prod_{j=0}^{n-1} (5^{2^j} + 1) \left\{ \begin{array}{l}
\equiv 0 \pmod{2^{n+2}} \\
\not\equiv 0 \pmod{2^{n+3}}
\end{array} \right.
\]

ii) If \( \alpha > 2 \) then the exponent of 5 modulo \( 2^\alpha \)

is \( 2^{\alpha-2} \);

iii) for \( \alpha > 2 \) the set of numbers

\[
\pm 1, \pm 5, \pm 5^2, \cdots, \pm 5^{2^{\alpha-2}-1}
\]

is a reduced system of residues modulo \( 2^\alpha \).
(N.B. When \( \alpha > 2 \) we know \( 2^\alpha \) has no primitive root; however, as this problem shows, 5 is the "next best thing" to a primitive root for \( 2^\alpha \).)

Remarks.

With respect to \(*2 (ii)*\) we note that there are cases where \( q \) may be a primitive root of \( p \) but not of \( p^2 \). However up to \( 1,001,321 \) all primes, with the single exception of \( 40,487 \), have least primitive roots which are also primitive roots of all higher powers. For \( 40,487 \) one finds the least primitive root 5 but also observes that \( 5^{40,486} \equiv 1 \pmod{40,487^2} \). (See Auppép and Yuguha [1971] and Riesel [1964].) It is interesting to note that 10 is a primitive root of 487 but not of \( 487^2 \); in fact, \( 10^{486} \equiv 1 \pmod{487^2} \). This does not contradict the above since 3 and not 10 is the least primitive root of 487.

Again, the exposition in this chapter owes much to Byx wTaf [1966].
xix  Special Primes and the Lucas-Lehmer Theorem

1. As earlier, we let \( F_n \) be the \( n \)-th Fermat number. (See \( \mathbf{III} \neq 9 \).) Thus \( F_n = 2^{2^n} + 1 \), \( n \geq 0 \).

Then, when \( n \geq 1 \),

i) if \( F_n \) is a prime then \( \left( \frac{3}{F_n} \right) = -1 \), where \( \left( \frac{3}{F_n} \right) \)

is the Legendre symbol;

ii) if \( 3^{\frac{F_n-1}{2}} \equiv -1 \pmod{F_n} \) then \( P_{F_n}(3) = F_n - 1 \)

and, therefore, \( F_n \) is prime (here \( P_{F_n}(3) \) is the exponent of 3 modulo \( F_n \));

iii) \( F_n \) is prime if and only if \( 3^{\frac{F_n-1}{2}} \equiv -1 \pmod{F_n} \).

2. Let \( p \) be a prime dividing \( F_n = 2^{2^n} + 1 \), \( n > 1 \).

Then:

i) \( P_{F_n}(2) = 2^{n+1} \);

ii) \( 2^{n+1} \mid p - 1 \) and \( \left( \frac{2}{p} \right) = 1 \);

iii) \( 2^{n+1} \mid \frac{p-1}{2} \) and, therefore, \( p = 1 + 2^{n+2} \cdot t \);
iv) every prime divisor of $F_n$, $n > 1$, must be of the form $1 + 2^{n+2} \cdot t$;

v) for each fixed $k$, $k \geq 1$, the sequence

$2^k + 1, 2 \cdot 2^k + 1, 3 \cdot 2^k + 1, 4 \cdot 2^k + 1, \ldots$

contains infinitely many primes.

3. i) Using #2(iv) one may factor $F_5$ rather quickly (compare with III #9(iii));

ii) (If computer is available) use #1(iii) to show $F_7$ is composite; (though Morehead found this result in 1905 it was not until 1971 that the factorization of $F_7$ was determined; see also the remarks at the end of III).

4. A number of the form $2^n - 1$ is called a Mersenne number and is denoted by $M_n$. A Mersenne prime is a prime Mersenne number.

i) If $M_n$ is prime then $n$ is prime;
ii) if \( p \) and \( q \) are primes and \( q = 2p + 1 \), 
\[ p \equiv 3 \pmod{4} \text{ then:} \]
\[ a) \ (\frac{q}{p}) = 1 \; \; b) \ q \nmid 2^p + 1 \; \; c) \ q \mid M_q ; \]
\[ \Box) \ 23 \mid M_{11} \; , \; 47 \mid M_{23} \; , \; 503 \mid M_{251} ; \]
\[ \checkmark) \ \text{the converse of (i) is false .} \]

5. (The Lucas-Lehmer Theorem)
As in #4 we write \( M_n = 2^n - 1 \). Further, for
\( n = 1, 2, \ldots \) let
\[ U_n = \frac{1}{2\sqrt{3}} \left\{ (1 + \sqrt{3})^n - (1 - \sqrt{3})^n \right\}, \quad V_n = (1 + \sqrt{3})^n + (1 - \sqrt{3})^n. \]
Then:

i) \( U_n, V_n \) are integers, \( V_n \) is even, and
\[ U_{n+2} = U_n + \frac{1}{2} V_n, \quad V_{n+2} = 6 U_n + V_n; \]

ii) for all \( m \geq 1, n \geq 1 \)
\[ a) \ 2 U_{m+n} = U_m V_n + V_m U_n; \quad d) \ U_{2n} = U_n V_n; \]
\[ b) \ (-2)^{n+1} U_n = U_m V_{m+n} - V_m U_{m+n}; \quad e) \ V_{2n} = V_n^2 + (-2)^{n+1}; \]
\[ c) \ 2 V_{m+n} = V_m V_n + 12 U_m U_n; \quad f) \ V_n^2 - 12 U_n^2 = (-2)^{n+2}; \]

\[ \checkmark \) if \( p \) is a prime larger than 3 then
a) \( U_p \equiv (3^p) \pmod{p} \); b) \( V_p \equiv 2 \pmod{p} \); c) \( p \mid U_{p-1} U_{p+1}; \]
w) if \( p \) is a prime larger than 3 and \( S_p \) is the set of integers \( n \) for which \( p | u_n \) then:

a) \( m, n \) in \( S_p \) imply \( m+n \) is in \( S_p \);

b) \( m, n \) in \( S_p \) and \( n < m \) imply \( m-n \) is in \( S_p \);

c) if \( \omega_p \) is the smallest element of \( S_p \) then
   1) \( \omega_p \leq p+1 \);
   2) \( n \) is in \( S_p \) if and only if \( \omega_p | n \);

v) if \( M_p = 2^p - 1 \) is prime then

a) \( 2 \nu_{2p} = 2 \nu_{2p-1} + 12 \nu_{2p-1} \equiv -8 \pmod{M_p} \);

b) \( \nu_{2p} = \nu_{2p-1}^2 - 4 \cdot 2^{2p+1-1} \);

c) \( \nu_{2p-1}^2 \equiv 4 \left( 2^{M_p-1} - 1 \right) \pmod{M_p} \);

d) \( M_p | \nu_{2p-1} \);

vi) if \( q \) is an odd prime and \( p \) is a prime divisor of \( M_q \), which, in turn, divides \( \nu_{2q-1} \) then:

a) \( p > 3 \);

b) \( p | \nu_{2q} \);

c) \( \omega_p | 2^q \);

d) \( \omega_p \nmid 2^{q-1} \);

e) \( \omega_p = 2^q \);

f) \( p = M_q \);
vii) there are integers \( s_1, s_2, \ldots \) such that
\[
s_i = 4, \quad s_{k+1} = s_k^2 - 2 \quad \text{for} \ k \geq 1
\]
and \( v_{2k} = 2^{k-1} s_k \) for \( k \geq 1 \);

viii) (the Lucas-Lehmer theorem)

if \( p \) is an odd prime larger than 3 then \( M_p \) is prime if and only if \( M_p \mid s_{p-1} \), where
\[
s_1 = 4, \quad s_{k+1} = s_k^2 - 2 \quad \text{for} \ k \geq 1
\]

ix) (the theorem of Lucas)

if \( p \) is an odd prime then \( M_p \) is prime if and only if \( M_p \mid t_{p-1} \), where
\[
t = 2, \quad t_{k+1} = 2t_k^2 - 1 \quad \text{for} \ k \geq 1.
\]

Remarks

Much of the information about large prime numbers \( M_p \) has been deduced from computations made possible by the Lucas-Lehmer theorem. See, for example, Sierpinski’s book *Elementary Theory of Numbers*. For a complete list of all
known Mersenne primes see the remarks in VIII. For an early history of such primes see Uhler [1952]. For more recent information see recent issues of the journal Mathematics of Computation.
**Pell Equation**

1. Let $\alpha$ be an irrational real number and $D$ be a positive non-square integer. Then:
   
   i- a) if $y$ is a non-zero integer then there is an integer $x$ satisfying $0 < x - ay < 1$;
   
   b) for each positive integer $m$ there are integers $x, y$, $0 < y \leq m$, such that
   
   \[|x - ay| < \frac{1}{m};\]
   
   c) there exist infinitely many distinct pairs $x, y$ such that $|x - ay| < \frac{1}{y}$;

   ii- a) if $\alpha = \sqrt{D}$ and $x, y$ is a pair of integers satisfying the inequality in (i-c) then
   
   \[|x^2 - Dy^2| < 1 + 2\sqrt{D};\]
   
   b) for some integer $k$ there are infinitely many integer pairs $x, y, y \geq 0$, such that $x^2 - Dy^2 = k$;
   
   c) there are distinct integer pairs $x_1, y_1$ and $x_2, y_2$ satisfying the conditions of (b) such that
   
   \[x_1 \equiv x_2, y_1 \equiv y_2 (\text{mod } k);\]
2. Consider the equation

\( (1) \ x^2 - Dy^2 = 1, \) \( D \) a positive non-square integer.

when \( x', y' \) satisfy (1) we call \( x' + y' \sqrt{D} \) a solution of (1). If \( x', y' \) are positive we call \( x' + y' \sqrt{D} \) a positive solution of (1) when it is a solution. Among all positive solutions \( x + y \sqrt{D} \) we call the one which is smallest the fundamental solution of (1). (Note that because of the irrationality of \( \sqrt{D} \) there can be only one smallest positive solution.) We denote the fundamental solution by \( x_0 + y_0 \sqrt{D} \). Then:
1) If \( x_1 + y_1 \sqrt{D} \) and \( x_2 + y_2 \sqrt{D} \) are solutions of (1) so also is \( x_3 + y_3 \sqrt{D} \) where

\[
x_3 + y_3 \sqrt{D} = (x_1 + y_1 \sqrt{D})(x_2 + y_2 \sqrt{D})
\]

ii) all non-positive solutions of (1) other than \( 1 + 0 \cdot \sqrt{D} \), \(-1 + 0 \cdot \sqrt{D} \) are obtainable from the positive solutions by making one or both of \( x, y \) negative;

iii) if \( x + y \sqrt{D} \) is a solution of (1) and if \( 1 < x + y \sqrt{D} \) then \( x > 0, y > 0 \);

iv) every positive solution of (1) is a positive integral power of the fundamental solution of (1);

v) as \( k \) runs over all integers (positive, negative, zero) then \( \pm (x_0 + y_0 \sqrt{D})^k \) runs over all solutions of (1).

3. Consider the equation

(2) \( x^2 - Dy^2 = -1 \), \( D \) a positive non-square integer. Then:

i) (2) is not always solvable;
ii) when (2) is solvable there is a smallest positive solution all odd integral powers of which are solutions and if taken with ± signs exhaust all solutions;

iii) if (2) is solvable and $x' + y' \sqrt{D}$ is the fundamental solution then $(x' + y' \sqrt{D})^2$ is the fundamental solution of (1).

4. Consider the equation

(3) $x^2 - Dy^2 = \sigma^2$, $D$ a positive non-square integer.

Then:

i) for each integer $\sigma$ the equation (3) has infinitely many solutions;

ii) if $x_1 + y_1 \sqrt{D}$ and $x_2 + y_2 \sqrt{D}$ are solutions of (3) and $x_3, y_3$ are defined by

$$\frac{x_3 + y_3 \sqrt{D}}{\sigma} = \frac{x_1 + y_1 \sqrt{D}}{\sigma} \cdot \frac{x_2 + y_2 \sqrt{D}}{\sigma}$$

then $x_3 + y_3 \sqrt{D}$ is a rational solution of (3) (i.e. $x_3, y_3$ are rational numbers and $x_3^2 - Dy_3^2 = \sigma^2$);
(iii) the \( x_3, y_3 \) in (ii) are not necessarily integers;

(iv) the \( x_3, y_3 \) in (ii) are integers if

\[ D \equiv 0 \pmod{\sigma^2}; \]

(v) if \( 4D \equiv \sigma^2 \pmod{4\sigma^2} \) then

a) \( \sigma \) is even, say \( \sigma = 2\rho \);

b) \( D = D'\rho^2 \), where \( D' \equiv 1 \pmod{4} \);

c) if \( x + y \sqrt{\sigma} \) is an integral solution of

(3) then \( \rho \mid x \) and \( \rho \), \( y \) have the same parity;

d) \( x_3 \) and \( y_3 \) in (ii) are integers;

(vi) if \( D \equiv 0 \pmod{\sigma^2} \) or \( 4D \equiv \sigma^2 \pmod{4\sigma^2} \)

then \( x^2 - Dy^2 = \sigma^2 \) has integral solutions and

if \( x_1 + y_1 \sqrt{\sigma} \), \( x_2 + y_2 \sqrt{\sigma} \) are such solutions so also is \( x_3 + y_3 \sqrt{\sigma} \), where \( x_3, y_3 \) are as defined

in (\( \ddagger \)) ; further, if \( x_0 + y_0 \sqrt{\sigma} \) is the smallest

integral solution with \( x_0 > 0, y_0 > 0 \) then all solutions \( x + y \sqrt{\sigma} \) are obtained by allowing

\( k \) to run over all the integers in the equation

\[
\frac{x + y \sqrt{\sigma}}{\sigma} = \pm \left( \frac{x_0 + y_0 \sqrt{\sigma}}{\sigma} \right)^k.
\]
5. (Miscellaneous)

i) For every rational number \( r \),
\[
\frac{D + r^2}{4} = \frac{2r}{D - r^2} \sqrt{D}
\]
is a rational solution of \((1)\);

ii) every rational solution of \((1)\) is of the form indicated in (i);

iii) the formula in (i) provides an integral solution for \( x^2 - 7y^2 = 1 \) when \( r = -\frac{7}{3} \);

iv) a parametric solution of \((3)\) is given by
\[
x = m^2 + Dn^2, \quad y = 2mn, \quad \sigma = m^2 - Dn^2.
\]

6. (A small application)

i) Give complete solutions to
\[
x^2 + 1 = 2y^2 \text{ and } x^2 - 1 = 2y^2;
\]

ii) let \( s_n \) be the sum of the lengths of the legs and \( h_n \) be the length of the hypotenuse of a Pythagorean triangle (a right triangle with integer length sides) whose legs are consecutive integers; show that the pair \( s_n, h_n \) is such a pair if and only if
\[ s_n + h_n \sqrt{2} = (1 + \sqrt{2})(3 + 2\sqrt{2})^n \]

for some positive integer \( n \);

ii) if \((x, x + 1, z)\) is a Pythagorean triple show \( f(x, x + 1, z) = (3x + 2z + 1, 3x + 2z + 2, 4x + 3z + 2)\) is also such a triple;

iii) all Pythagorean triples with consecutive integer legs appear in the sequence
\[(3, 4, 5), f(3, 4, 5), f^2(3, 4, 5), f^3(3, 4, 5), \ldots \]
where \( f \) is as in (iii);

iv) compute the 1st four terms of the sequence in (iiv).

Remarks

Equations of the form \( x^2 - Dy^2 = a \) are called Pell equations, though some authors feel the reference to be sufficiently unreliable as to refuse to call them by this name. An elementary exposition of these equations will be found in Gelfond [1961]. The result in \#6(iiv) is proved in
quite a different manner in Sierpinski’s delightful little book *Pythagorean Triangles*. The method used here derives from Carmichael [1915]. The Pell equation arose earlier, in our chapter on continued fractions, see xiii #17 (vii). If one examines the diagram in xi #15 one finds all the Pythagorean triangles with consecutive integer legs on the horizontal line through (3, 4, 5). This may easily be confirmed by comparing the diagram with #6 (w) above.
Weyl's Theorem on Uniform Distribution

In the following all functions have domain $[0, 1]$ and the sequences $\{s_n\}$ are to satisfy $0 \leq s \leq 1$ for all $n$.

Definition: $\{s_n\}$ is uniformly distributed if for every pair of $a, b$, $0 \leq a < b \leq 1$ the number, $n(a, b)$, of $s_1, \ldots, s_n$ lying in $[a, b]$ satisfies $\lim_{n \to \infty} \frac{n(a, b)}{n} = b - a$.

1. Define the characteristic function $\chi_I$ of a subinterval $I$ of $[0, 1]$ by

$$\chi_I(x) = \begin{cases} 1 & \text{for } x \text{ in } I; \\ 0 & \text{otherwise}. \end{cases}$$

Then:

- $a) \sum_{m=1}^{n} \chi_{[a, b]}(s_m) = n(a, b)$;
- $b) \int_0^1 \chi_{[a, b]}(x) \, dx = b - a$;
ii) If for every $f$ which is a characteristic function of a subinterval of $[0,1]$ it is true that \[
\lim_{n \to \infty} \frac{1}{n} \sum_{m=1}^{n} f(s_m) = \int_{0}^{1} f(x) \, dx \]
then \{s_n\} is uniformly distributed;

iii) the converse of (ii) is also true.

Definition: When the limit expression in \( \#_1(ii) \) holds we write \( f(s_n) \sim \int f \).

2. Let $f$ be Riemann integrable and suppose that for each $\varepsilon > 0$ there are Riemann integrable functions $g$ and $h$ such that $g \leq f \leq h$, $0 \leq \int_{0}^{1} (h(x) - g(x)) \, dx < \varepsilon$, $g(s_n) \sim \int g$, $h(s_n) \sim \int h$.

Then $f(s_n) \sim \int f$.

3. If \{s_n\} is uniformly distributed then for every Riemann integrable function $f$ it is true that $f(s_n) \sim \int f$. 
4. i) By treating real and complex parts separately we see that the result of \( \ast 3 \) remains valid for \( f \) a Riemann integrable complex valued function of a real variable;

\[ f(x) = e^{2\pi i k x}, \text{ } k \text{ a positive integer}, \text{ then } f(s_n) \sim 0. \]

5. Let \( P \) be the proposition "\( e^{2\pi i k s_n} \sim 0 \) for all \( k \geq 0 \)" and let \( T \) be an arbitrary trigonometric polynomial with zero constant term; i.e.

\[ T(x) = \sum_{k \geq 1} (a_k \cos 2\pi k x + b_k \sin 2\pi k x); \text{ then:} \]

i) if \( P \) then \( T(s_n) \sim 0 \);

\[ \text{ii) if for all such } T \text{ as described } T(s_n) \sim 0 \text{ then } P; \]

\[ \text{iii) } P \text{ if and only if } T(s_n) \sim 0 \text{ for all trigonometric polynomials with zero constant term}; \]

\[ \text{iv) the proposition in (iii) is true even if on the right we eliminate the condition "with zero constant term";} \]
vi) if \( P \) then \( f(s_n) \to f \) for all continuous \( f \);  

vi) if \( P \) then \( \{ s_n \} \) is uniformly distributed;  

vii) (Weyl's theorem)  
\[ \{ s_n \} \text{ is uniformly distributed if and only if } \lim_{n \to \infty} \frac{1}{n} \sum_{m=1}^{n} e^{2\pi i k s_m} = 0 \text{ for all } k \geq 0. \]

6. i) If \( \alpha \) is irrational and \( s_n \) is the fractional part of \( n\alpha \), i.e. \( s_n = n\alpha - [n\alpha] = (n\alpha) \), then \( \{ s_n \} \) is uniformly distributed;  

ii) If \( \alpha \) is irrational and \( \beta \) is arbitrary and \( \sigma = (n\alpha + \beta) \) then \( \{ s_n \} \) is uniformly distributed.

7. i) The sequence \( \{ s_n \} \) is uniformly distributed if and only if for all \( a, 0 \leq a \leq 1 \), \( \lim_{n \to \infty} \frac{n(i\alpha)}{n} = a; \)  

ii) let \( \{ \beta_n \} \) be uniformly distributed and suppose \( |\alpha_n - \beta_n| < \frac{1}{n} \) for all \( n \); then \( \{ \alpha_n \} \) is uniformly distributed;
iii) Let $S$ be a countable subset of $[0, 1]$; then $S$ is dense in $[0, 1]$ if and only if some enumeration of $S$ is uniformly distributed.

8. Let $\alpha_1, \ldots, \alpha_q$ be complex numbers and set $\alpha_q = 0$ for $q \leq 0$ and for $q > q$.

Then, for $1 \leq H \leq q$,

i) $H \sum_{1 \leq q \leq H} \alpha_q = \sum_{0 \leq p < H} \left\{ \sum_{0 \leq \eta < H} \alpha_{p-\eta} \right\}$;

ii) $\sum_{p \leq H} \alpha_{p-s} = \sum_{1 \leq q \leq H} \alpha_q \bar{\alpha}_q + \sum_{1 \leq H \leq q} \left( H - H \right) \sum_{1 \leq q \leq H} \left( \alpha_q \bar{\alpha}_{q-H} + \bar{\alpha}_q \alpha_{q-H} \right)$.

9. Let $\alpha_1, \ldots, \alpha_q$ be complex numbers and define $\alpha_j$ for $j \leq 0$, $j > q$ as in #8. Further, suppose $1 \leq H \leq q$. Then:

$$H^2 \left| \sum_{1 \leq q \leq H} \alpha_q \right|^2 \leq (H + q - 1) \left\{ H \sum_{1 \leq q \leq H} \left| \alpha_q \right|^2 + 2 \sum_{0 \leq \eta < H} \left( H - H \right) \sum_{1 \leq q \leq H} \alpha_q \bar{\alpha}_{q-H} \right\}.$$ 

10. i) If $e^{2\pi i (m - n)} \sim 0$ for all positive integers $n$, then $e^{2\pi i m} \sim 0$.
ii) If \( \{ s_{n+h} - s_n \} \) is uniformly distributed for each positive integer \( h \) then \( \{ s_n \} \) is uniformly distributed.

ii. (Weyl) If \( f(x) = a_1x^1 + \cdots + a_n \) and for some \( j \), \( a_j \) is irrational, then the fractional parts \( \{ f(n) \} \) of \( f \) are uniformly distributed.

Remarks
The work of this chapter follows the expositions given by Hardy [1949] and Cassels [1957]. Vinogradoff proved in 1937 that if one replaces \( n \) by \( p_n \), the \( n \)th prime, in \#6 (i) then the resulting sequence \( \{ (\alpha p_n) \} \) is uniformly distributed. By using Vinogradoff's method Rhin has recently proved \#11 with \( n \) replaced by \( p_n \). The interested reader should consult the review of Rhin's paper:

For a proof of 6(i) not dependent on Weyl's theorem but making use of continued fractions one might consult Niven's *Irrational Numbers*. Weyl originally proved his theorem in 1916 and it has long been considered an outstanding contribution to the theory. The result in 7(iii) is a very special case of a general theorem proved by John von Neumann [1925]. The reader might consult Koksma [1936] for this and many other aspects of the material of this chapter.
xxii Möbius Functions

1. Let \( f(x) = x + x^2 + x^3 + \ldots \) and define \( a_1, a_2, a_3, \ldots \) to be that sequence of integers for which

\[
x = a_1 f(x) + a_2 f(x^2) + a_3 f(x^3) + \ldots
\]

when one carries out the operations on the right in a purely formal manner. Then:

\( i-a) \quad a_1 = 1 , \quad \sum_{d \mid m} a_d = 0 \quad \text{for } m > 1 ; \)

\( b) \quad \text{if } (s, t) = 1 \text{ then } a_{st} = a_s a_t ; \)

\[
a_{p^k} = \begin{cases} 
1 & \text{for } k = 0 , \\
-1 & \text{for } k = 1 , \\
0 & \text{for } k > 1 , \quad \text{where } p \text{ is a prime;}
\end{cases}
\]

\( c) \quad a_n = \begin{cases} 
1 & \text{for } n = 1 , \\
(-1)^k \text{ for } n \text{ the product of } k \text{ distinct primes ,} \\
0 & \text{for } n \text{ divisible by a square } > 1 ;
\end{cases}
\]

\( ii-a) \quad x = \sum_{m=1}^{\infty} \frac{a_m x^m}{1 - x^m} ; \)
6) \( \frac{1}{10} = \frac{1}{9} - \frac{1}{99} - \frac{1}{999} - \frac{1}{9999} + \frac{1}{99999} - \cdots ; \)

\[ \phantom{6) \frac{1}{10}} + \frac{1}{999999} - \frac{1}{9999999} + \cdots \]

\[ \phantom{6) \frac{1}{10}} + \frac{1}{111111} - \frac{1}{11111111} + \cdots \]

(This function \( a_n \) was first introduced by A. F. Möbius [1831] in just this way. Nowadays one writes \( \nu(n) \) rather than \( a_n \) and defines the function by (i-d) above. Quite recently Gian-Carlo Rota [1963-4] has shown how the Möbius function arises quite naturally in a considerably wider setting and with many applications in combinatorial analysis. Rota's work has been extended and generalized in a great proliferation of papers in the last 12 years.)

Definition. Define the function \( \nu \) by:

\[ \nu(n) = \begin{cases} 
1 & \text{for } n = 1; \\
(1)^k & \text{for } n \text{ the product of } k \text{ distinct primes}; \\
0 & \text{for } n \text{ divisible by a square } > 1;
\end{cases} \]
1. e. define \( N \) by \( N(n) = a_n \) for \( n \geq 1 \), \( a_n \) as in \(*1\). 

2. i) \( N \) is a multiplicative function; i.e. if \((s, t) = 1\) then \( N(st) = N(s) N(t) \); 

ii) If \( f \) is multiplicative then 
\[ \sum_{d \mid n} N(d)f(d) = \prod_p \left(1 - f(p)\right) \]
where \( p \) in the index denotes a prime number; 

a) \[ \sum_{d \mid n} N(d) = 0 \text{ for } n > 1; \]

b) \[ \sum_{d \mid n} \frac{N(d)}{d} = \prod_p \left(1 - \frac{1}{p}\right) \]

c) \[ \sum_{d \mid n} \frac{N(d)}{d} = \prod_p \left(1 - \frac{1}{p}\right) = \frac{\varphi(n)}{n} = \frac{1}{n} \sum_{d \mid n} N\left(\frac{n}{d}\right)d; \]

d) \[ \sum_{d \mid n} N(d)^2 = 2^t, \text{ where } t \text{ is the number of distinct prime factors of } n. \]

3. i) (Möbius inversion) 
\[ f(n) = \sum_{d \mid n} g(d) \text{ if and only if } g(n) = \sum_{d \mid n} N(d)f\left(\frac{n}{d}\right) \]
a) define \( \Lambda(n) \) to be \( \ln p \) when \( n \) is a power of the prime number \( p \) and to be \( 0 \) otherwise; 
then 

1) \[ \ln n = \sum_{d \mid n} \Lambda(d); \]
2) \( \Lambda(n) = -\sum_{d|n} \nu(d) \ln d \); 

(\( \Lambda(n) \) is called the Mangoldt function.)

b) \( n = \sum_{d|n} \varphi(d) \);

c) \( F(n) = \prod_{d|n} f(d) \) if and only if 

\[ f(n) = \prod_{d|n} F\left( \frac{n}{d} \right)^{\nu(d)}; \]

d) \( F_n(x) = \prod_{d|n} \left( x^d - 1 \right)^{\nu(d)} \), where \( F_n(x) \) is as in XIV\#17;

e) define \( \overline{\varphi}(n) \) by:

\[ \overline{\varphi}(1) = 1, \quad \varphi(n) = \sum_{d|n} \overline{\varphi}(d) \] for \( n > 1 \);

then \( \overline{\varphi}(n) = \begin{cases} 0 & \text{if } n \text{ is divisible by a cube } > 1; \\
(-2)^t & \text{if } n \text{ is cubefree and the squarefree part of } n \text{ is divisible by exactly } t \text{ different primes};
\end{cases} \]

ii) (Shapiro)

if \( \psi \) is a real function defined on \([0,1]\) then

if \( f(n) = \sum_{r|n}^\infty \psi\left( \frac{r}{n} \right) \), \( g(n) = \sum_{r|n} \psi\left( \frac{r}{n} \right) \) then

\[ f(n) = \sum_{d|n} \nu(d) g\left( \frac{n}{d} \right); \]

a) \( \mathcal{N}(n) = \sum_{\substack{r|n \equiv 1 \\ r \equiv n}} e^{2\pi irr \over n}; \)
b) let $S_k(n)$ be the sum of the $k^{th}$ powers of the positive integers prime to $n$; then

$$S_k(n) = n^k \sum_{d \mid n} \frac{1}{\phi(d) \frac{1}{d^k}};$$

1) $S_1(n) = \frac{1}{2} n \varphi(n)$, $n > 1$;

2) $S_2(n) = \frac{1}{3} n^2 \varphi(n) + \frac{1}{6} n \prod_{p \mid n} (1 - \frac{1}{p})$, $n > 1$;

3) $S_3(n) = \frac{1}{4} n^3 \varphi(n) + \frac{1}{4} n^2 \prod_{p \mid n} (1 - \frac{1}{p})$, $n > 1$;

4) $1^k + 2^k + \ldots + n^k = n^k \sum_{d \mid n} \frac{S_k(d)}{d^k} = \sum_{d \mid n} d^k S_k(n)$;

c) let $\omega(n)$ be the product of those integers prime to $n$ and not exceeding $n$; then

$$\omega(n) = \prod_{d \mid n} \frac{n}{\phi(d)} \sum_{d \mid n} \frac{\omega(d)}{d^k};$$

(iii) (Prachar)

let $k_1, \ldots, k_N$ be $N$ numbers of which $\alpha$ are equal to 1 and suppose $f$ is defined for each $k_i$; then

if $S_d = \sum_{d \mid k_i} f(k_i)$ then $\sum_{d \mid n} \frac{1}{\phi(d)} S_d = \alpha f(1)$;

a) let $\varphi(x, y)$ be the number of integers not exceeding $x$ which are divisible by no prime not exceeding $y$ and let $\tau_y = \prod_{p \mid y} p$; then

$$\varphi(x, y) = \sum_{d \mid \tau_y} \frac{\omega(d)}{d^k} \left[ \frac{x}{d} \right];$$
1) $\sum_{m \leq n} N(m) \left( \frac{m}{n} \right) = 1$ ;
2) $\left| \sum_{m \leq n} \frac{N(m)}{m} \right| \leq 1$ ;
3) $\pi(x) - \pi(\sqrt{x}) + 1 = \lfloor x \rfloor - \sum_{p \leq x} \lfloor \frac{x}{p} \rfloor + \sum_{p \leq x} \lfloor \frac{x}{p^2} \rfloor - \cdots$, where $p_1, \ldots, p_\omega$ are the primes not exceeding $\sqrt{x}$.

4. i) For $h$ a function of two variables
$\sum_{m \leq x} N(n) h(x, mn) = h(x, 1)$ ;

ii) (Shapiro) let $P$ be completely multiplicative; i.e. $P(ab) = P(a)P(b)$ for all $a, b$; then $g(x) = \sum_{n \leq x} P(n) f(n) \iff$ and only if $f(x) = \sum_{n \leq x} N(n) P(n) g(n)$ ;

iii) given $\sum_{m, n \leq x} |f(mnx)| = \sum_{\nu \leq x} \tau(n) |f(\nu x)|$ we have $q(x) = \sum_{m \leq x} f(mx) \iff$ and only if $f(x) = \sum_{n \leq x} N(n) g(nx)$ ;

here $\tau(n)$ is the number of divisors of $n$ ;

iv) (Halberstam and Roth) let $\mathcal{D}$ be divisor closed; i.e. $\mathcal{D}$ is a set such that $\mathcal{D}$ contains all integral divisors of any of its elements; then $F(d) = \sum_{d \in \mathcal{D}, d \leq x} G(d)$ if and only if $G(d) = \sum_{t \in \mathcal{D}, t \leq x} N(t) F(td)$. 
Some Analytic Methods

In the following we shall often write expressions like $O(f(x))$, where $f$ is a positive real function. Whenever we write this we intend it to stand for an unspecified complex valued function of a real variable, say $g(x)$, with the following property: there exist constants $x_0, A$ such that $g(x)$ and $f(x)$ are defined for all $x \geq x_0$ and, for such values of $x$,

$$|g(x)| \leq Af(x).$$

1. Let $f$ be a complex valued function of a real variable and suppose $M, N$ are integers with $M < N$. Further, put $F(m) = \sum_{k=M+1}^{N} f(k)$, $F(M) = 0$. Then, for any real function,

i) (Abel partial summation formula)

$$\sum_{m=M+1}^{N} f(m) g(m) = F(N) g(N+1) - \sum_{m=M+1}^{N} F(m)(g(m+1) - g(m))$$

$$= F(N) g(N) - \sum_{m=M+1}^{N} F(m)(g(m+1) - g(m)).$$
It will be noted that this formula is a finite analogue of the integration by parts formula
\[ \int_a^b u'v = uv\bigg|_a^b - \int_a^b uv'. \]
Indeed, if we put \( \Delta h(n) = h(n) - h(n-1) \), we may write the formula
\[ \sum_{m=M+1}^N (\Delta F(m)) q(m) =
F(m)q(m)\bigg|_M^N - \sum_{m=M+1}^N F(m)(\Delta g(m+1)). \]

\( \text{ii) if } q \text{ is monotonic and non-negative,} \]
\[ \sum_{m=M+1}^N f(m)q(m) \leq \begin{cases} 
q(N) \max_{M \leq m \leq N} |F(m)| \text{ if } q \text{ is decreasing,} \\
2q(N) \max_{M \leq m \leq N} |F(m)| \text{ if } q \text{ is increasing.}
\end{cases} \]

\( \text{iii) if } q \text{ tends monotonically downward to } 0 \text{ as } n \to \infty, \text{ and if } F \text{ is bounded, then} \)

a) \[ \sum_{n=1}^\infty f(n)q(n) \text{ converges;} \]

b) \[ \sum_{n=1}^\infty f(n)q(n) = \sum_{n=1}^\infty f(n)q(n) + O(q([x])) ; \]

\( \text{iv) if } \lambda_1, \lambda_2, \ldots \text{ is an unboundedly increasing sequence of real numbers and } q \text{ has a continuous derivative for } x \geq \lambda_1 \text{ then,} \)
putting \( F(x) = \sum_{\lambda_1 \leq \lambda_m \leq x} f(m) \), we have

\[
\sum_{\lambda_1 \leq \lambda_m \leq x} f(m) g(x_m) = F(x) g(x) - \int_{\lambda_1}^{x} F(t) g'(t) \, dt;
\]

\( \text{v) if } a \text{ is a positive integer and } g \text{ has a continuous derivative for } x \geq a \text{ then} \)

\[
\sum_{a \leq m \leq x} g(m) = \int_{a}^{x} g(t) \, dt + \int_{a}^{x} t-[t] g'(t) \, dt + g(a) -(x-[x]) \, g(x);
\]

\( \text{vi) if } a \text{ is a positive integer and } g \text{ is a monotone function with a continuous derivative for } x \geq a \text{ then} \)

\[
\sum_{a \leq m \leq x} g(m) = \int_{a}^{x} g(t) \, dt + O(|g(a)| + |g(x)|); 
\]

\( \text{vii) if } a \text{ is a positive integer and } g \text{ is a continuously differentiable function for } x \geq a \text{ and if } g \text{ tends monotonically to } 0 \text{ as } x \to \infty \text{ then} \)

\[
\sum_{a \leq m \leq x} g(m) = \int_{a}^{x} g(t) \, dt + c + O(1g(x)1),
\]

where \( c = \int_{a}^{\infty} (t-[t]) \, g'(t) \, dt \) is independent of \( x \).
2. (Applications)

i) \( \sum_{n \leq x} \frac{1}{n^s} \approx \frac{1}{1-s} x^{1-s} + C + O(x^{-s}), s > 0, s \neq 1, \)
where \( C \) is a suitable constant;

ii) \( \sum_{n \leq x} \frac{1}{n} = \ln x + \gamma + O(x^{-1}), \) where \( \gamma \) is Euler's constant (approximately equal to 0.57721) and
\( \gamma = 1 - \int_1^{\infty} \frac{t - \lfloor t \rfloor}{t^2} \, dt = \lim_{n \to \infty} \left\{ \sum_{m=1}^{n} \frac{1}{m} - \ln n \right\}; \)

(\text{It is not known whether or not } \gamma \text{ is rational.})

iii) \( \sum_{n \leq x} \ln n = x \ln x - x + O(\ln x); \)

iv) \( \sum_{n \leq x} \frac{1}{n} = O(x); \)

v) \( \sum_{p \leq x} \frac{\ln p}{p} + O(1) = \frac{1}{x} \sum_{p \leq x} \ln p \left\{ \left[ \frac{x}{p} \right] + \left[ \frac{x}{p^2} \right] + \cdots \right\} \)
\[ = \frac{1}{x} \sum_{n \leq x} \left[ \frac{x}{n} \right] \Lambda(n) = \frac{1}{x} \sum_{n \leq x} \ln n = \ln x + O(1), \]
where \( p \) is a prime and \( \Lambda(n) \) is 0 unless \( n \) is a power of a prime \( p \) when it is \( \ln p; \)

(see XXII \( \neq 3(i-a)) \)

vi) \( \sum_{p \leq x} \frac{\ln p}{p} = \ln x + O(1) = \sum_{n \leq x} \frac{\Lambda(n)}{n} + O(1); \)

vii) \( \sum_{n<p<n^2} \frac{\ln p}{p} = \int_{N}^{N^2} \frac{\Pi(t)\ln t - 1}{t^2} \, dt + O(1). \)
3. (Chebyshev's theorem of 1849)

Suppose \( \lim_{x \to \infty} \frac{\pi(x)}{x/\ln x} \) exists and equals \( \beta \). Then:

i) if \( \beta < 1 \) then

\[
\ln N + O(1) = \sum_{n < p \leq N} \frac{\ln p}{p} = \int_{N}^{N^2} \Pi(t) \frac{\ln t - 1}{t^2} \, dt + O(1)
\]

\[
< \frac{1 + \beta}{2} \int_{N}^{N^2} \left( \frac{1}{t} - \frac{1}{t \ln t} \right) \, dt + O(1) < \frac{1 + \beta}{2} \ln N + O(1),
\]

which is false;

ii) if \( \beta > 1 \) then a similar contradiction to that in (i) arises;

iii) if \( \lim_{x \to \infty} \frac{\pi(x)}{x/\ln x} \) exists then that limit is 1.

(This result was proved by Chebyshev in 1849 but it was not until 1896 that it was proved the limit exists. In that year the Belgian, de la Vallée Poussin, and the Frenchman, Jacques Hadamard, independently published proofs that the limit does exist. The result

\[
\lim_{x \to \infty} \frac{\pi(x)}{x/\ln x} = 1
\]

has come to be known as the Prime Number Theorem. The first proofs made heavy use of the theory of
functions of a complex variable and it was not until 1948 that the first so called "elementary" proofs - that is, those not using complex variable theory - were given by the Swedish mathematician Atle Selberg and the Hungarian mathematician Paul Erdős. For further information with respect to this theorem and its ramifications the reader might consult Hardy & Wright [1962], Trost [1968], Specht [1956], Prachar [1957], Landau [1953], or Levinson [1969].

4. i) \[ \sum_{\substack{n \leq N \atop d | n}} n = \frac{d}{2} \left( \frac{N}{d} + O(1) \right)^2 \]

ii) If \( N^* \) is the number of positive proper irreducible fractions with denominator not exceeding \( N \) then

\[ N^* = \sum_{\substack{n \leq N \atop \gcd(n, d) = 1}} \frac{N(d)}{d} \sum_{\substack{n \leq N \atop d | n}} n \]

iii) \( N^* \), as in (ii), satisfies

\[ N^* = \frac{N^2}{2} \left( \sum_{n=1}^{\infty} \frac{1}{n^2} \right)^{-1} + N^2 g(N) \]

for some function \( g(N) \) which tends to 0 as \( N \to \infty \).
iv) if $N'$ is the total number of positive proper fractions with denominator not exceeding $N$ then
\[
\lim_{N \to \infty} \frac{N'}{N} = \left( \sum_{n=1}^{\infty} \frac{1}{n^2} \right)^{-1};
\]

v) the probability of 2 randomly chosen integers being relatively prime is \(\frac{6}{\pi^2}\).

5. (Infinite products)

The infinite product \(\prod_{j=1}^{\infty} a_j\) is said to converge to \(\alpha\) if \(\alpha \neq 0\) and \(\lim_{n \to \infty} \prod_{j=1}^{n} a_j = \alpha\). When such a non-zero \(\alpha\) exists we say the product converges and in the contrary case that it diverges.

i) \(x \leq \ln \frac{1}{1-x} = \sum_{n=1}^{\infty} \frac{x^n}{n}\), for \(0 \leq x \leq \frac{1}{2}\);

ii) if \(0 \leq x_j < 1\) for all \(j\) then
\(\prod_{j=1}^{\infty} \ln \frac{1}{1-x_j}\) converges if and only if
\(\prod_{j=1}^{\infty} x_j\) converges;

iii) if \(0 \leq x_j < 1\) for all \(j\) then
\(\prod_{j=1}^{\infty} \frac{1}{1-x_j}\) converges if and only if \(\prod_{j=1}^{\infty} x_j\) converges.
6. Suppose \( f \) is a completely multiplicative (real or complex valued) number theoretic function; i.e., \( f(ab) = f(a)f(b) \) for all integers \( a \) and \( b \). Then if \( \sum_{j=1}^{\infty} f(j) \) is absolutely convergent we have:

i) \( |f(j)| \leq 1 \) for all \( j \);

ii) \( \left| \sum_{j=1}^{\infty} f(j) - \prod_{p \leq m} (1 - f(p)^{-1}) \right| \leq \sum_{j=m+1}^{\infty} |f(j)| \);

iii) \( \prod_{p} (1 - f(p))^{-1} = \sum_{j=1}^{\infty} f(j) \).

7. In (i-a) below we show \( \sum_{n=1}^{\infty} \frac{1}{n^s} \) converges for \( s > 1 \); we denote the sum of this series, in this case, by \( \mathcal{L}(s) \). In (b)-(f) \( s \) is to be larger than 1.

i-a) \( \sum_{n=1}^{\infty} \frac{1}{n^s} \) converges for \( s > 1 \);

b) \( \frac{1}{s-1} < \mathcal{L}(s) < 1 + \frac{1}{s-1} \);

c) \( (s-1) \mathcal{L}(s) \to 1 \) as \( s \to 1^+ \);

d) \( \mathcal{L}(s) = \prod_{p} \left( 1 - p^{-s} \right)^{-1} \);

e) \( \ln \mathcal{L}(s) = \sum_{p} \sum_{n=1}^{\infty} \frac{1}{np^ns} \);

f) \( 0 \leq \ln \mathcal{L}(s) - \sum_{p} \frac{1}{ps} < 1 \);
ii-a) one can use (i-c) and (d) to prove the existence of infinitely many primes; 

b) one can use (i-f) to show \( \sum_p \frac{1}{p^s} \) converges for \( s > 1 \) and diverges for \( s = 1 \).

(The proof in (ii-a) of the infinitude of primes goes back to Euler and this proof already contains the germ of the idea developed by Dirichlet to prove the theorem concerning the infinitude of primes in an arithmetic progression. In the next two problems we extend these notions a little further and obtain some special cases of the Dirichlet theorem.)

8. Define \( \chi : \mathbb{Z} \to \{0, 1, -1\} \) by

\[
\chi(n) = \begin{cases} 
0 & \text{if } n \equiv 0 \pmod{2} \\
1 & \text{if } n \equiv 1 \pmod{4} \\
-1 & \text{if } n \equiv 3 \pmod{4} 
\end{cases}
\]
Further, put \( L(s) = \prod_{n=1}^{\infty} \frac{\chi(n)}{n^s} \).

Then:

i-a) \( L(s) \) exists for \( s > 0 \);

b) \( 0 < L(s) < 1 \) for \( s > 0 \) and \( \frac{2}{3} < L(s) \) for \( s \geq 1 \);

c) \( L(s) \) is continuous at 1;

d) \( \zeta(s) L(s) \to \infty \) as \( s \to 1^+ \);

e) \( \lim_{s \to 1^+} \prod_{p \equiv 3 \pmod{4}} (1 - p^{-2s})^{-1} \) exists;

f) \( \zeta(s) = \prod_p \left( 1 - \frac{1}{p^s} \right)^{-1} \)

\( \quad \prod_{p \equiv 1 \pmod{4}} (1 - p^{-s})^{-1} \prod_{p \equiv 3 \pmod{4}} (1 - p^{-s})^{-1} \); 

and \( L(s) = \prod_p \left( 1 - \frac{\chi(p)}{p^s} \right)^{-1} = \)

\( \prod_{p \equiv 1 \pmod{4}} (1 - p^{-s})^{-1} \prod_{p \equiv 3 \pmod{4}} (1 + p^{-s})^{-1} \); 

- there are infinitely many primes of each of the forms \( 4k+1, \ 4k+3 \);

ii) one can derive the result of (i-g) along the following lines:

a) \( \ln L(s) = \sum_p \frac{\chi(p)}{p^s} + O(1) \);

b) \( \ln \zeta(s) = \sum_p \frac{1}{p^s} + O(1) \);
c) \[ \ln g(s) + \chi^{-1}(a) \ln L(s) = \]
\[
\begin{cases}
2 \sum_{p \equiv 1 \pmod{4}} \frac{1}{p^s} + O(1) & \text{for } a = 4k + 1; \\
2 \sum_{p \equiv 3 \pmod{4}} \frac{1}{p^s} + O(1) & \text{for } a = 4k + 3;
\end{cases}
\]
d) there are infinitely many primes of each of the forms \(4k+1, 4k+3\).

9. Define the four number theoretic functions \(\chi_j, 0 \leq j \leq 3\), by the condition
\[ \chi_j(n) = \chi_j(a) \text{ when } n \equiv a \pmod{4}, 0 \leq j \leq 3, \]
and the table

<table>
<thead>
<tr>
<th>(a)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>i</td>
<td>-i</td>
<td>-1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>

<td>-1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>1</td>
<td>-i</td>
<td>i</td>
<td>-1</td>
</tr>
</tbody>
</table>

The \(i\) is just \(\sqrt{-1}\). Thus, for example,
\[ \chi_1(17) = \chi_1(2) = i, \quad \chi_2(43) = \chi_2(3) = -1. \]
i-a) Each $\chi_j$ is completely multiplicative;

b) for $a \not\equiv 0 \pmod{s}$,

\[ \sum_{n \equiv n \pmod{s}} \chi^{-1}(a) \chi(n) = \begin{cases} 4 & \text{if } a \equiv n \pmod{s} \\ 0 & \text{otherwise} \end{cases} \]

c) if $L_0(\chi) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n}$, $L_1(\chi) = \sum_{n=1}^{\infty} \frac{\chi(n) \ln n}{n}$

then, for $\chi \not\equiv \chi_0$, the two series converge to non-zero sums;

d) for $\chi \not\equiv \chi_0$, $\sum_{\mathfrak{n} \equiv \mathfrak{n} \pmod{s}} \frac{\chi(n)}{n} = L_0(\chi) + O\left(\frac{1}{\chi}\right)$

and $\sum_{\mathfrak{n} \equiv \mathfrak{n} \pmod{s}} \frac{\chi(n) \ln n}{n} = L_1(\chi) + O\left(\frac{\ln \chi}{\chi}\right)$;

e) for $\chi \not\equiv \chi_0$, $\sum_{\mathfrak{n} \equiv \mathfrak{n} \pmod{s}} \frac{\mathfrak{M}(n) \chi(n)}{n} = O(1)$;

f) for $\chi \not\equiv \chi_0$,

\[ \sum_{\mathfrak{n} \equiv \mathfrak{n} \pmod{s}} \frac{\mathfrak{M}(n) \chi(n)}{n} = \sum_{\mathfrak{d} \equiv \mathfrak{d} \pmod{s}} \frac{\mathfrak{M}(\mathfrak{d}) \chi(\mathfrak{d})}{\mathfrak{d}} \left\{ L_1(\chi) + O\left(\frac{\ln \chi/\mathfrak{d}}{\chi/\mathfrak{d}}\right) \right\} = O(1); \]

ii-a) for $\chi \not\equiv \chi_0$,

\[ \sum_{\mathfrak{p} \equiv \mathfrak{p} \pmod{s}} \frac{\chi(\mathfrak{p}) \ln \mathfrak{p}}{\mathfrak{p}} = \sum_{\mathfrak{p} \equiv \mathfrak{p} \pmod{s}} \frac{\chi(\mathfrak{p}) \Lambda(\mathfrak{p})}{\mathfrak{p}} = O(1); \]

b) for $a \not\equiv 0 \pmod{s}$,

\[ \sum_{\mathfrak{p} \equiv \mathfrak{p} \pmod{s}} \frac{\ln \mathfrak{p}}{\mathfrak{p}} = \frac{1}{4} \sum_{\mathfrak{p} \equiv \mathfrak{p} \pmod{s}} \frac{\chi(\mathfrak{p}) \ln \mathfrak{p}}{\mathfrak{p}} = \frac{1}{4} \ln \chi + O(1); \]

c) there are infinitely many primes of each of the forms

\[ 5n + 1, 5n + 2, 5n + 3, 5n + 4. \]
Numerical Characters and the Dirichlet Theorem

In problems #8, #9 of xxiii we met functions \( \chi, \chi_0, \ldots, \chi_4 \). These functions are special cases of a class of functions called characters. The \( \chi \) of #8 is a mod 4 character and the \( \chi_j \) of #9 are mod 5 characters. In this chapter we introduce the notion of mod \( k \) characters for arbitrary positive integers \( k \) and will use them, much as was done in #8, #9 of xxiii, to prove the Dirichlet theorem on primes in arithmetic progressions.

Definition. A completely multiplicative complex valued number theoretic function of period \( k \) which is zero precisely on those integers not prime to \( k \) is called a (numerical) mod \( k \) character.
1. (Elementary properties)

i) The function $\chi_0$ defined by

$$\chi_0(a) = \begin{cases} 1 & \text{if } (a, k) = 1 \\ 0 & \text{otherwise,} \end{cases}$$

is a mod $k$ character; this character $\chi_0$ is called the principal mod $k$ character;

ii) $\chi(1) = 1$ for all mod $k$ characters;

iii) if $\chi$ is a mod $k$ character and $(a, k) = 1$ then $\chi(a)$ is a $\varphi(k)$th root of unity;

iv) the function $\chi$ defined in \textit{xxiii}#8 is a mod 4 character;

v) the functions $\chi_j$, $0 \leq j \leq 3$, defined in \textit{xxiii}#9 are mod 5 characters;

vi) there are only finitely many mod $k$ characters; in fact, no more than $\varphi(k)^{\varphi(k)}$ (we shall see in \textit{#3} (ii) that this bound is much too large);
vii) if \( \chi \) is a mod \( d \) character and \( k \equiv dn \)
then \( \chi^* \) defined by \( \chi^*(n) = \begin{cases} \chi(n) \text{ for } (n, k) = 1; \\
0 \text{ otherwise,} \end{cases} \)
is a mod \( k \) character; \( \chi^* \) is called the
mod \( k \) extension of \( \chi \);

viii) \( \sum_{n=1}^{k} \chi(n) = 0 \) for \( \chi \) any non-principal
mod \( k \) character;

ix) if \( \chi_1 \) and \( \chi_2 \) are mod \( k \) characters so
also are \( \chi_1 \chi_2 \) and \( \overline{\chi}_1 \), where \( \overline{\chi}_1(a) = \overline{\chi_1(a)} \),
the bar on the right denoting the complex
conjugate function;

x) \( \chi \chi_1 \) runs over all mod \( k \) characters
as \( \chi \) does.

2. (Properties leading to a deeper result)

i) Let \( p \) be an odd prime, \( \beta \) be a positive
integer, and \( q \) be a primitive root of \( p^\beta \); define \( \chi \)
by \( \chi(n) = \begin{cases} 0 \text{ for } (n, p^\beta) = 1; \\
e^{2\pi i n/q(p^\beta)} \text{ for } n \equiv q^\lambda (\text{mod } p^\beta), 0 \leq \lambda < \varphi(p^\beta); \end{cases} \)
then a) \( \chi \) is a mod \( p^9 \) character;

b) if \( (d', p^9) = 1 \) and \( d' \neq 1 \pmod{p^9} \)
then \( \chi(d') \neq 1 \);

c) if \( (d', k) = 1, d' \neq 1 \pmod{p^9}, \) and \( p^9 \)
divides \( k \) then there is a mod \( k \) character \( \chi^* \)
such that \( \chi^*(d) \neq 1 \);

ii) let 4 be the highest power of 2 which
divides \( k \) and let \( \chi^* \) be the mod \( k \) extension of
the mod 4 character \( \chi \) defined in \( \text{XXIII} \# 8 \); then
if \( d' \equiv -1 \pmod{4} \) then \( \chi^*(d) \neq 1 \);

iii) let \( 2^\alpha, \alpha \geq 3, \) be the highest power of 2
which divides \( k \) and define \( \chi \) by

\[
\chi(n) = \begin{cases} 
0 & \text{for } n \text{ even;} \\
\exp\left( \frac{2\pi it}{2^{\alpha-2}} \right) & \text{for } n \equiv (-1)^{\frac{n-1}{2}} \cdot 5^t \pmod{2^\alpha}, 0 \leq t < 2^{\alpha-2}; 
\end{cases}
\]

then

a) \( \chi \) is a mod \( 2^\alpha \) character;

b) if \( (d, k) = 1 \) and \( d \neq \pm 1 \pmod{2^\alpha} \) then
there is a mod \( k \) character \( \chi^* \) such that
\( \chi^*(d) \neq 1 \);
iw) if \( (d, k) = 1 \) and \( d \neq 1 \pmod{k} \) then there is a mod \( k \) character such that \( \chi(d) \neq 1 \).

3. i) Let \( c \) be the number of mod \( k \) characters;
then \( \sum_{\chi} \chi(a) = \begin{cases} c & \text{if } a \equiv 1 \pmod{k} \\ 0 & \text{if } a \not\equiv 1 \pmod{k} \end{cases} \);
ii) there are exactly \( \varphi(k) \) mod \( k \) characters;
iii) when \( (a, k) = 1 \),
\[ \sum_{\chi} \chi(a)^{-1} \chi(n) = \begin{cases} \varphi(k) \text{ for } a \equiv n \pmod{k} \\ 0 \text{ otherwise} \end{cases} \];
iv) if \( (a, k) = 1 \) then
\[ \sum_{\chi} \chi(a) \chi(n) = \begin{cases} \varphi(k) \text{ for } a \equiv n \pmod{k} \\ 0 \text{ otherwise} \end{cases} \].

4. (Miscellaneous)
Let \( (a, k) = 1 \) and let \( m \) be the exponent of a modulo \( k \). Then for each mod \( k \) character \( \chi \) it is true that \( \chi(a)^m = \chi(a^m) = \chi(1) = 1 \); thus \( \chi(a) \) is an \( m^\text{th} \) root of unity. In this
problem we see that as \( \chi \) runs over the mod \( k \) characters none of the \( m \) \( m^{th} \) roots of unity is slighted in its number of appearances - i.e. they each appear \( \frac{\varphi(k)}{m} \) times. Let \( \omega \) be an arbitrary \( m^{th} \) root of unity and suppose it appears \( N \) times. Then

\[
i) \quad \sum_{j=1}^{m} \left( \frac{\chi(a)}{\omega} \right)^j = \begin{cases} m & \text{if } \chi(a) = \omega \\ 0 & \text{otherwise} \end{cases}
\]

\[
ii) \quad Nm = \sum_{\chi} \sum_{j=1}^{m} \left( \frac{\chi(a)}{\omega} \right)^j = \varphi(k).
\]

In the next six problems the Dirichlet theorem is proved.

5. Each of the three series

\[
\sum_{n=1}^{\infty} \frac{\chi(n)}{n}, \quad \sum_{n=1}^{\infty} \frac{\chi(n) \ln n}{n}, \quad \sum_{n=1}^{\infty} \frac{\chi(n)}{\sqrt{n}}
\]

converges when \( \chi \) is a non-principal mod \( k \) character; denoting the sums by \( L_0(\chi), L_1(\chi), L_2(\chi) \) respectively we have
\[
\sum_{n \leq x} \frac{\chi(n)}{n} = L_0(X) + O\left(\frac{1}{X}\right); \\
\sum_{n \leq x} \frac{\chi(n) \ln n}{n} = L_1(X) + O\left(\frac{\ln x}{x}\right); \\
\sum_{n \leq x} \frac{\chi(n)}{\sqrt{n}} = L_2(X) + O\left(\frac{1}{\sqrt{x}}\right).
\]

6. Suppose \( \chi \) is any real non-principal mod \( k \) character. Define \( F \) and \( G \) by

\[
F(n) = \sum_{d \mid n} \chi(d), \quad G(x) = \sum_{n \leq x} \frac{F(n)}{\sqrt{n}}.
\]

Then:

i) \( F \) is multiplicative and

\[
F(p_1^{a_1} \ldots p_s^{a_s}) = \prod_{i=1}^{s} \chi(p_i^{a_i}),
\]

ii) for all \( n \), \( F(n) \geq 0 \), \( F(n^2) \geq 1 \);

iii) \( G(x) \to \infty \) as \( x \to \infty \);

iv) \( G(x) = \sum_{d \leq x} \frac{\chi(d)}{\sqrt{d} \sqrt{x}} = \sum_{d \leq x} \frac{1}{\sqrt{d}} + \sum_{d \leq x} \frac{1}{\sqrt{d} \sqrt{x}} \sum_{d \leq x} \frac{\chi(d)}{\sqrt{d}} \)

v) \( G(x) = 2 \sqrt{x} L_0(X) + O(1) \);

vi) if \( \chi \) is any real non-principal mod \( k \) character then

\[
L_0(X) = \sum_{n=1}^{\infty} \frac{\chi(n)}{n} \neq 0.
\]
7. i) \( L_0(\chi) \sum_{n \leq x} \frac{\Lambda(n) \chi(n)}{n} = O(1) \) for \( \chi \neq \chi_0 \) (the \( \chi \) here need not be real);

ii) suppose \( \chi \) is a non-real character and that \( L_0(\chi) = 0 \); then putting \( g(x) = \sum_{n \leq x} \frac{\Lambda(n) \chi(n)}{n} \ln \frac{x}{n} \) we have

\[
\begin{align*}
\text{a)} & \quad g(x) = -x L_1(\chi) + O(\ln x) ; \\
\text{b)} & \quad x \ln x = -x L_1(\chi) \sum_{n \leq x} \frac{\Lambda(n) \chi(n)}{n} + o(x) ; \\
\text{iii)} & \quad \text{for any } \chi \neq \chi_0 , \\
L_1(\chi) \sum_{n \leq x} \frac{\Lambda(n) \chi(n)}{n} = \begin{cases} 
-\ln x + O(1) & \text{for } L_0(\chi) = 0 ; \\
O(1) & \text{for } L_0(\chi) \neq 0 .
\end{cases}
\end{align*}
\]

8. For \( \chi \neq \chi_0 \),

\[
\sum_{p \leq x} \frac{\chi(p) \ln p}{p} = \begin{cases} 
-\ln x + O(1) & \text{if } L_0(\chi) = 0 ; \\
O(1) & \text{if } L_0(\chi) \neq 0 .
\end{cases}
\]

9. Let \( N \) be the number of non-principal \( k \)-characters for which \( L_0(\chi) = 0 \). Then:

i) if \( N \neq 0 \) then \( N \geq 2 \) ;
11) if \( Q(x) = \varphi(k) \sum_{\substack{p \equiv \chi \pmod{k} \atop p \neq 1}} \frac{\ln p}{p} \) then
\[
0 \leq Q(x) = \sum_{\chi} \sum_{p \neq x} \frac{x(p) \ln p}{p} = (1 - N) \ln x + O(1);
\]
i, if \( x \neq x_0 \), then \( L_0(x) \neq 0 \);
\[
\sum_{p \neq x} \frac{x(p) \ln p}{p} = O(1) \text{ when } x \neq x_0;
\]
(note that (6) tells us the supposition made in \( \pi(x) \) is in fact not realizable; i.e., that the number \( N \) of non-principal characters for which \( L_0(x) = 0 \) is itself 0).

10. (The Dirichlet Theorem)

For \( (a, k) = 1 \),
\[
\varphi(k) \sum_{\substack{p \equiv a \pmod{k} \atop p \neq 1}} \frac{\ln p}{p} = \sum_{\chi} \chi(a)^{-1} \sum_{p \neq x} \frac{x(p) \ln p}{p} = \ln x + O(1)
\]
and, therefore, there are infinitely many primes in the arithmetic progression
\( a, a + k, a + 2k, a + 3k, \ldots \).
Remarks.

1. The theory of numerical characters is but a small part of the general theory of characters in the theory of Abelian groups. It is for this reason we have used the word "numerical".

2. The interested reader might wonder if each residue class modulo \( \mathbb{Z} \) gets its "fair share" of primes. Since there are \( \varphi(\mathbb{Z}) \) possible residue classes for the primes this would mean that each class got \( \frac{1}{\varphi(\mathbb{Z})} \) of the primes. The asymptotic Dirichlet theorem says

\[
\left( \sum_{p \equiv a \pmod{\mathbb{Z}}} 1 \right) \left( \frac{x}{\ln x} \right)^{-1} \to \frac{1}{\varphi(\mathbb{Z})} \quad \text{as} \quad x \to \infty.
\]

Using this one may immediately deduce the prime number theorem \( \pi(x) \left( \frac{x}{\ln x} \right)^{-1} \to 1 \) as \( x \to \infty \) and then conclude \( \left( \sum_{p \equiv a \pmod{\mathbb{Z}}} 1 \right) \left( \pi(x) \right)^{-1} \frac{1}{\varphi(\mathbb{Z})} \) as \( x \to \infty \). Thus each class does equally well.
For an elementary, though quite involved, proof of the asymptotic Dirichlet theorem the reader might consult Specht [1956].

3. Our proof of the Dirichlet theorem follows Shapiro [1950] and also makes use of ideas of Rademacher [1964], Hasse [1950], and Prachar [1957].
SOLUTIONS
I The Game of Euclid & the Euclidean Algorithm

~ Solutions ~

1. i, ii) The derived sets are
\{m, n - m\}, \{m, n - 2m\}, \ldots, \{m, n - tm\},
where \(tm < (t + 1)m\);

iii) since we are assuming \(m \leq n\) we must
have \(\{a, b\} = \{m, n - sm\}\) for some positive
integer \(s\); now any common divisor of \(n\) and \(m\)
clearly divides \(m\) and \(n - sm\) and conversely;
thus \((n, m) = (m, n - sm) = (a, b)\);

iv) since negative integers are not permitted
and each move reduces one of the two elements
it must happen, after a finite number of
steps, that one of the elements is reduced
to 0; the other, by (iii), must then be \((m, n)\).
2. (i) This is clear;

(ii) if a player starting with \( \{2,5\} \) moves to the minimal derived set \( \{2,1\} \) then the other player will immediately win by moving to \( \{0,1\} \);

(iii) if there is but one derived set the proposition is true; otherwise, since we are assuming there is a winning strategy for A and since one of A or B must ultimately make the move from the minimal derived set, the advantage must lie in either making or not making this move, and for A to do anything other than asserted enables B to decide who will move from the minimal derived set and thus transfers to B the winning strategy;
iv) since \( m < a < m < 2m \) the only possible move from \( \{a, m\} \) is to \( \{a-m, m\} \); hence, \( r = a - m \) and
\[
\frac{m}{r} = \frac{m}{a-m} = \frac{a}{m} - 1 > \frac{1}{\tau - 1} = \tau.
\]

3. i) Since one is not able to win in one move from a position \( \{m, n\} \), \( 1 < \frac{n}{m} < \tau \), it is enough to show that when A starts from \( \{m, n\}, \frac{n}{m} > \tau \), then he may either win in one move or leave to B a position with \( 1 < \frac{n}{m} < \tau \), from which, by \#2 (iv), B's sole move is to a position with ratio > \( \tau \) from which the process is repeated; when \( \frac{n}{m} > 2 \) there are at least the two moves
\[
\{m, n\} \rightarrow \{m, r\} \quad \{m, m+r\}, \quad 0 \leq r < m,
\]
where \( r \) is the remainder obtained when one divides \( n \) by \( m \); if \( r = 0 \), A may win in one move by moving to \( \{m, r\} \); otherwise,
since (by an elementary calculation) \( \tau \) is strictly between \( \frac{m}{r} \) and \( \frac{m+r}{m} \), \( A \) moves to that position for which the ratio lies strictly between 1 and \( \tau \); when \( \tau < \frac{n}{m} < 2 \) \( A \) moves to \( \{m,r\} \);

\[ \text{ii) this follows from (i).} \]

4. By \#1(iii) we know \((r_0, r_1) = (r_1, r_2) = (r_2, r_3) = \cdots = (r_{n-1}, r_n) = (r_n, 0) = r\).

5. In \#4 each \( r_j, j \geq 2 \), is a linear combination of \( r_{j-1}, r_{j-2} \); thus starting at the bottom of the Euclidean algorithm and solving for \( r_n \) first in terms of \( r_{n-1}, r_{n-2} \) and then in terms of \( r_{n-2}, r_{n-3} \) etc. we ultimately find \( r_n \) expressed in the form \( cr_0 + dr_1 \), where \( c \) and \( d \) are integers; since \( 0 < r_n \leq \min \{ r_0, r_1 \} \) exactly one of \( c, d \) is \( \leq 0 \).
if $c < 0, d = 0$ or $c = 0, d > 0$

then $r_0 = r_1 = r_2$ so $r_n = 2r_0 - 1 \cdot r_1$;

if $c > 0, d < 0$ then $r_n = cr_0 - |d| r_1$;

if $c < 0, d > 0$ then $r_n = (sr_1 - |c|) r_0 + (d - sr_0) r_1$

and we may select $s$ so that

$sr_1 - |c| > 0, d - sr_0 < 0$.

6. i) The proof is by induction; since

$u_6 = 13 > 10$ it is true for $n = 1$; supposing

it to be true for $n$ we have

$u_{5(n+1)+1} = u_{5n+5} + u_{5n+4} = 2u_{5n+4} + u_{5n+3}$

$= 3u_{5n+3} + 2u_{5n+2} = 5u_{5n+2} + 3u_{5n+1}$

$= 8u_{5n+1} + 5u_{5n} > 8u_{5n+1} + 2(u_{5n} + u_{5n-1}) = 10u_{5n+1}$

>$10^{n+1}$, and thus it is also true for $n+1$;

ii) reading the Euclidean algorithm from

bottom to top we see
\[ r_{n-1} \geq r_n + r_{n-1} \geq r_n + 1 \geq u_2 \]
\[ r_{n-2} \geq r_{n-1} + r_n \geq u_2 + 1 = u_3 \]
\[ r_{n-3} \geq r_{n-2} + r_{n-1} \geq u_3 + u_2 = u_4 \]
\[ \ldots \]
\[ r_1 \geq r_2 + r_3 \geq u_{n-1} + u_{n-2} = u_n ; \]

(iii) If the number of divisions \( n \) is 1, this is clear; otherwise suppose \( 0 < r_1 < r_0 \) and the first step has \( r_1 \) as divisor and \( r_1 \) has \( t \) base 10 digits; then, by (ii), \( r_1 \geq u_n \) and, if \( m \) is such that
\[ 5m + 1 \leq n \leq 5(m+1) \]
then \( r_1 \geq u_n \geq u_{5m+1} \geq 10^m \) so \( t \geq m + 1 \geq \frac{1}{5} n \)
and \( n \leq 5t ; \)

(iv) Direct calculation;

(v) By (ii), \( b \geq u_{st} \) and since \( b \) has \( t \) base 10 digits \( u_{st} \) has \( t \) or fewer base 10 digits ;
vi) by induction \(|u_{n+1}^2 - u_n u_{n+2}| = 1\) for all \(n\) and \\
\(\frac{u_{n+2}}{u_n} < \tau\) \((> \tau)\) when \(n\) is even (odd); hence \\
\(|\frac{u_{n+2}}{u_n} - \tau| < |\frac{u_{n+1}}{u_n} - \frac{u_{n+2}}{u_{n+1}}| = \frac{1}{u_n u_{n+1}} < \frac{1}{u_n^2}\); for further \\
details see II \#3, 5;

vii) for \(n = 4\) we have \(u_4 = 55 > 10 \cdot 5 = 10u_4\);
assuming true for \(n\) we have
\[u_{n+5} = 5u_{n+1} + 3u_n = u_n\left\{5\tau + 3 + 5\left(\frac{u_{n+1}}{u_n} - \tau\right)\right\} \geq u_n \left(\frac{15}{2} + 3 - \frac{1}{5}\right) > 10u_n\] for \(n \geq 4\) (using (vi));

viii) for \(t = 4\), \(u_{20} = 10946 > 10^4\);
assuming true for \(t\), then, by (vii),
\[u_{5(t+1)} = u_{st+5} > 10u_{st} > 10 \cdot 10^t = 10^{t+1}\];

ix) by (viii) when \(t\) is at least 4, \(u_{st}\) has
more than \(t\) base 10 digits while, by (v), if
the process starting with \(a\) and \(b\), \(a > b\),
\(b\) having \(t\) base 10 digits, takes \(st\) steps
then \(u_{st}\) has no more than \(t\) base 10 digits;
the conclusion follows.
II The Golden Mean - Solutions

1. Let \( \frac{m}{r} = \tau \); then \( \tau = 1 + \frac{1}{\tau} \) so \( \tau^2 = \tau + 1 \) and, therefore, \( \tau = \frac{1 \pm \sqrt{5}}{2} \); since \( \tau > 0 \) we must have \( \frac{m}{r} = \tau = \tau \).

2. By the above \( \tau^2 = \tau + 1 \); dividing by \( \tau \) and then subtracting \( \tau \) from both sides yields \( \tau^{-1} = \tau - 1 \); finally since \( \tau \tau' = -1 \) the last relationship follows.

3. If \( \frac{m}{r} < \tau \) then
   \[
   \frac{m + r}{m} = 1 + \frac{1}{m/r} > 1 + \frac{1}{\tau} = \frac{\tau + 1}{\tau} = \frac{\tau^2}{\tau} = \tau;
   \]
   similarly if \( \frac{m}{r} > \tau \) then \( \frac{m + r}{m} < \tau \). Finally, if \( \alpha \) is between \( \frac{m}{r} \) and \( \frac{m + r}{m} \) then
   \[
   |\alpha - \tau| \leq \left| \frac{m + r}{m} - \frac{m}{r} \right| = \left| \frac{mr + r^2 - m^2}{mr} \right|
   = \left| 1 + \frac{m}{r} - \left( \frac{m}{r} \right)^2 \right|;
   \]
now since we may select integers \( m \) and \( r \) so that \( \frac{m}{r} \) is as close as we like to \( \tau \) we see that 
\[ |\alpha - \tau| \] 
is smaller than every positive number, hence \( \alpha = \tau \).

4. i) The inequality is true for the 1st two terms; supposing it to be true up to and including the \( n^{th} \) term we have \( \beta \geq (n-1)c \), \( \alpha \geq nc \) when \( \frac{\beta}{\delta}, \frac{\alpha}{\beta} \) are the \( n-1^{st} \) and \( n^{th} \) terms respectively; now the \( n+1^{st} \) term has a numerator \( \alpha + \beta \) which is 
\[ \geq (n-1)c + nc \geq (n+1)c; \]
the remainder of the assertion follows from this and the fact that the typical denominator is the previous numerator;

\( \hat{\nu} \) let the terms be \( \frac{a}{\delta}, \frac{a+b}{a}, \frac{2a+b}{a+b} \);
then direct calculation yields the result;
iii) this follows immediately from (ii);

iv) if any two consecutive terms of the sequence are equal then, by \( *_1 \), all terms are equal to \( \tau \) and the sequence converges to \( \tau \); otherwise by \( *_3 \), \( \tau \) lies strictly between each consecutive pair of terms and hence, using (i) and (iii), the sequence converges to \( \tau \).

5. i) Immediate from the definition of the sequence in \( *_4 \);

ii) this follows by induction from (i) and the truth for \( n = 0 \); from (i) we see that any divisor of \( u_{n+2} \) and \( u_{n+1} \) is also a divisor of \( u_{n+1} \) and \( u_{n} \) (\( = u_{n+2} - u_{n+1} \));

iii) this follows from \( *_4(\ddagger) \) and the fact that \( u_1^2 - u_0 u_2 = 1 - 2 = -1 = (-1)' \);
iv) this follows from *4(i) since $c = 1$

\[ |\frac{u_{n+1}}{u_n} - \tau| \leq |\frac{u_{n+1}}{u_n} - \frac{u_{n+2}}{u_{n+1}}| = \frac{|u_{n+1}^2 - u_n u_{n+2}|}{u_n u_{n+1}} \]

\[ = \frac{1}{u_n u_{n+1}} < \frac{1}{u_n^2} ; \]

vi) this follows from (iv) and (v) or from

*4(iv) ;

6. i-a) This is true for $n = 1$ by *2 ; suppose true for $n$; then $\tau^{n+2} = \tau \tau^{n+1} = \tau(u_{n-1} + u_n \tau) = u_{n-1} \tau + u_n \tau^2 = (u_{n-1} + u_n) \tau + u_n = u_n + u_{n+1} \tau$

and the induction is complete ;

6) for $n = 1$ we have $-\tau^{-2} = \tau^{-1} - 1$ which follows also from *2; suppose true for $n$; then

\[ (-1)^{n+1} \tau^{-(n+1)} = -\tau^{-1}(-1)^n \tau^{-(n+1)} = -\tau^{-1}(u_n \tau^{-1} - u_{n-1}) = -u_n \tau^{-2} + u_{n-1} \tau^{-2} = u_n (\tau^{-1} - 1) + u_{n-1} \tau^{-1} = u_{n+1} \tau^{-1} - u_n \]

and the induction is complete ;
ii) for \( n = 0 \) this is clear; for \( n \geq 1 \) we add the expressions in (i-a) and (b) to obtain
\[
u_n (\tau + \tau^{-1}) = \tau^{n+1} + (-1)^n \tau^{-m+1};
\]
since \( \tau + \tau^{-1} = \tau - \tau' = \sqrt{5} \) and \( \tau^{-1} = -\tau' \) we have
\[
u_n = \frac{1}{\sqrt{5}} \{ \tau^{n+1} - \tau'^{n+1} \}.
\]

7. i) Equality of the areas implies
\[(u + v)r = mv = (m + r)u\]

and, therefore,
\[
\frac{v}{u} = \frac{m+r}{m} \quad \text{and} \quad \frac{u+v}{u} = 1 + \frac{v}{u} = 1 + \frac{m}{r} = \frac{m+r}{r};
\]

thus \( \frac{v}{u} = \frac{m}{r} = \frac{m+r}{m} = \tau \),

where we have used \#i for the last equality.

ii) in this case \( m = u + v \) so
\[
\frac{m}{r} = \frac{m+r}{m} = \frac{m+r}{u+v} = \tau
\]
and the conclusion follows.
8. Consider the regular pentagon shown; then, successively, we see:

\[(b + c)^2 + (a/2)^2 = D^2;\]
\[\frac{b + c}{a/2} = \frac{b}{d};\]
\[b^2 + d^2 = a^2;\]
\[2d + a = D;\]
\[d = e;\] thus we conclude:

\[D = a, \quad d + e = \frac{a}{c}, \quad a' = \frac{a}{c^2}, \quad D' = \frac{a}{c};\]

when \(a = 1\) this yields \(D = c.\)

9. Considering the proof as given in the solution to #8 we see that the lines are as marked at the right. This yields the result as stated. The continuation is clear.
10. For any integral value of \( m \) the dissections indicated below are correct.

\[
\tau^{m+1} \quad \tau^m
\]

\[
\tau^{m+2} \quad \tau^{m+1} \quad \tau^{m+2}
\]

They are correct since \((\tau^{m+2})^2 = \tau^{m+1}(\tau^{m+1}+\tau^{m+2})\).

11. The model seems to form a 13 by 34 rectangle; but the area of the square is \(21^2 = 441\) and the area of the rectangle is \(13 \cdot 34 = 442\); the model does not indicate this discrepancy since the extra unit of area is distributed along the main diagonal and it would require an extremely accurate model to reveal the difficulty.

12. a) \( \tau = 1 + \frac{1}{\tau} \) since \( \tau^2 = 1 + \tau \) and successively replacing \( \tau \) on the right by
1 + \frac{1}{\epsilon} \text{ yields the string of equalities; if the pieces yield } \frac{u_{n+1}}{u_n} \text{ up to the } n^{th} \text{ term then the next term is just } 1 + \frac{1}{\frac{u_{n+1}}{u_n}} = 1 + \frac{u_n}{u_{n+1}} = \frac{u_{n+2}}{u_{n+1}} \text{ so the expression for the general term is correct;}

6) by #5 (vi) we know \frac{u_{n+1}}{u_n} \rightarrow \epsilon \text{ so the implied limiting process does yield } \epsilon.

13. i) This is immediate for } n = 1, 2 \text{ and all } m; \text{ suppose true for each of } n, m \text{ and all } m; \text{ then } u_{m+(n+1)} = u_{m+n-1} + u_{m+n} = u_{m-1}u_{n-2} + u_mu_{n-1} + u_{m-1}u_{n-1} + u_mu_n = u_{m-1}(u_{n-2} + u_{n-1}) + u_m(u_{n-1} + u_n) = u_{m-1}u_n + u_mu_{n+1};

ii) clear for } m = 1 \text{ so assume true for } m; \text{ then } u_{n(m+1)-1} = u_{nm+n-1} = u_{nm-1}u_{n-2} + u_{nm}u_{n-1} \text{ and, therefore, since } u_{n-1} \text{ divides } u_{nm-1} \text{ we may conclude } u_{n-1} \text{ divides } u_{n(m+1)-1};
iii) noting \((n, m)\) divides each of \(n, m\) part (ii) shows \(u_{(n, m)-1}\) divides \((u_{n-1}, u_{m-1})\); now there are integers \(x\) and \(y\) such that 
\((n, m) = nx - my\) so \(u_{nx-1} = u_{(n(m)+my-1} = u_{(n,m)-1}u_{my-2} + u_{(n,m)}u_{my-1}\) and, since 
\((u_{n-1}, u_{m-1})\) divides each of \(u_{nx-1}\) and \(u_{my-1}\), it divides \(u_{(n,m)-1}u_{my-2}\) and is prime to \(u_{my-2}\); thus \((u_{n-1}, u_{m-1})\) divides \(u_{(n,m)-1}\) and the proof is complete.

14. For \(n=2\) we have \(\left(\begin{array}{cc} 1 & 1 \\ 1 & 0 \end{array}\right)^2 = \left(\begin{array}{cc} 2 & 1 \\ 1 & 1 \end{array}\right)\) and the result is correct; suppose true for \(n\), then
\(\left(\begin{array}{cc} 1 & 1 \\ 1 & 0 \end{array}\right)^{n+1} = \left(\begin{array}{cc} 1 & 1 \\ 1 & 0 \end{array}\right)\left(\begin{array}{cc} u_n & u_{n-1} \\ u_{n-1} & u_{n-2} \end{array}\right) = \left(\begin{array}{cc} u_{n+1} & u_n \\ u_n & u_{n-1} \end{array}\right)\).

15. i) The contributors to \(g(n)\) not containing \(n\) are precisely the contributors to \(g(n-1)\), while those containing \(n\) are precisely the contributors to \(g(n-2)\) with \(n\) adjoined;
ii) this is true for \( n = 1, 2 \) by direct calculation and the recurrence of (i) shows that the equality continues since it is the same as the Fibonacci recurrence;

iii) each \( k \) element subset of \( \{1, 2, \ldots, n\} \) corresponds uniquely to a marking of \( k \) elements of \( \{1, 2, \ldots, n\} \) with a 1 and the remaining \( n-k \) elements with a 0; such a subset will contribute to \( f(n, k) \) precisely when no two consecutive 1's appear;

iv) in (iii) the \( n-k \) 0's may be thought to define \( n-k+1 \) boxes; the number of ways of putting \( k \) 1's into these boxes as described is just the number of strings of 0's and 1's discussed in (iii); i.e., it is equal to \( f(n, k) \);
v) by (iv) it is just the number of ways of choosing \( k \) of \( n-k+1 \) objects and this is \( \binom{n-k+1}{k} \) when \( n-k+1 \geq k \) and is 0 otherwise;

\[ \nu_n = q(n-1) = \sum_{k=0}^{n-1} \binom{n-1}{k} = \sum_{k=0}^{n-1} \binom{n}{k} ; \]

vi) this follows immediately from (vi).

16. i) By the ratio test the series converges for \( \lim_{n \to \infty} \frac{u_{n+1}}{u_n} |x| < 1 \); since the limit is \( \tau |x| \) we see that the series converges for \( |x| < \frac{1}{\tau} \); calculation shows \( U - xU - x^2U = 1 \) so \( U = \frac{1}{1-x-x^2} \) when \( |x| < \frac{1}{\tau} \);

\[ \nu \] let \( r = \tau \), \( s = \tau' \); then \( r+s = 1 = -rs \)

and \( \frac{1}{1-x-x^2} = \frac{r/(r-s)}{1-rx} - \frac{s/(r-s)}{1-sx} ; \)
iii) expanding \( \frac{r}{1-rx} \) and \( \frac{s}{1-sx} \) on the right of (ii) yields
\[
\frac{1}{1-x-x^2} = \frac{1}{r-s} \sum_{n=0}^{\infty} (r^{n+1} - s^{n+1}) x^n
\]
\[
= \frac{1}{\sqrt{s}} \sum_{n=0}^{\infty} (\tau^{n+1} - \tau'^{n+1}) x^n
\]
and comparison with \( U \) yields the conclusion;

iv) put \( x = .01 \) in \( U \), making use of (i);

v) by induction.
III Prime Factorizations ↔ Primes

~ Solutions ~

1. For the integer \( n = 2 \) the integer 2 is itself
   a prime divisor of \( n \). If the proposition is
   false let \( N \) be the smallest positive integer
   \( > 1 \) for which it is false. Then \( N \) is not prime
   so \( N = ab \), where \( 1 < a < N, 1 < b < N \). This
   implies \( a \) has a prime factor which is then
   a prime factor of \( N \). This contradicts our
   assumption that the proposition is false.

2. True for \( n = 2 \). If false for some integer
   let \( N \) be the smallest integer for which it is
   false. Then \( N \) is not prime so \( N = ab, 1 < a < N, 
   1 < b < N \). Thus each of \( a, b \) have prime factor-
   izations. Putting the factorizations of \( a \) and
   \( b \) together gives a prime factorization for \( N \).
This is a contradiction so the proposition must be true.

3. Suppose \( p \) is a prime dividing \( ab \); if \( p \) does not divide \( a \) then \( (p, a) = 1 \) so, by \( \text{I}^*5 \), there are integers \( x \) and \( y \) such that \( 1 = px - ay \); multiplying this equation by \( 6 \) yields \( 6 = px6 - aby \); now if \( p | ab \) then \( p \) divides the right and, therefore, the left side of this last equation.

(Alternate proof)

Let \( S \) be the set of positive integers \( n \) for which, for a given prime \( p \), there exists a \( b \) satisfying

\( p \) divides \( nb \) and \( p \) divides neither \( n \) nor \( b \).

We show \( S \) is empty by an induction argument. Certainly \( 1 \) is not in \( S \). Suppose no integer \( < n \) is in \( S \). Let \( p \) divide \( nb \) and suppose \( n = pt + q, 0 \leq q < p, b = ps + r, 0 \leq r < p \).
Then \( nb = p (pts + tr + sq) + qr \) so \( p \) divides \( qr \). Since \( q < n \), either \( p \) divides \( q \) or \( p \) divides \( r \). In either event \( p \) divides one of \( n, b \) so \( n \) is not in \( S \). Thus \( S \) is empty and the proposition is proved.

4. For \( n = 2 \) this is clear. Suppose true for all positive integers \( > 1 \) and \( < n, n > 2 \). Let \( n = p_1 \ldots p_k = q_1 \ldots q_s \) where the \( p_i \) and \( q_i \) are primes. Then by the finite extension of \( \#3 \), \( p_i \) divides one of \( q_1, \ldots, q_s \) and hence equals one of them. Suppose, without loss of generality, \( p_1 = q_1 \). Then \( \frac{n}{p_1} \) is an integer smaller than \( n \). If \( \frac{n}{p_1} = 1 \) then, since \( n \) is prime, the proposition is true for \( n \). Otherwise \( 2 \leq \frac{n}{p_1} < n \) so the proposition is true for \( \frac{n}{p_1} \); i.e. \( p_2, \ldots, p_k \) are just the \( q_2, \ldots, q_s \) in some order. Thus \( p_1, \ldots, p_k \) are just the \( q_1, \ldots, q_s \) in some order.
and the proposition is true for $n$. By induction the proposition is true for all $n \geq 2$.

5. By $\#2$ there is a prime $p$ which divides $1 + n!$. Since no prime dividing $n!$ may divide $1 + n!$ and since all primes $\leq n$ divide $n!$ it must be the case that $p > n$. Hence since there can be no largest prime there must be infinitely many of them.

6. Since $1 + p_1 \cdots p_k$ must have a prime factor differing from each of $p_1, \ldots, p_k$ and since the same argument shows that every finite collection of primes fails to exhaust all primes the number of primes is not finite.
7. Such a string is afforded by
\[(k+1)! + 2, \ldots, (k+1)! + (k+1).\]

8. Since the product of any finite number of \(4k+1\) primes is again a \(4k+1\) number and since \(4p_1 \cdots p_k - 1\) is not of the form \(4k+1\) we conclude that among the prime factors of \(4p_1 \cdots p_k - 1\) there must be a \(4k+3\) prime. Since, by the argument of \#6 above, no finite set of primes can exhaust all \(4k+3\) primes there must be infinitely many of them.

9. i) \(F_2 = 2^2 + 1 = 5 \equiv 7 \pmod{10}\);
    suppose \(2^{2n} + 1 = F_n \equiv 7 \pmod{10}\);
    then \(2^{2n} \equiv 6 \pmod{10}\) and, therefore,
    \(F_{n+1} = 2^{2n+1} + 1 = (2^{2n})^2 + 1 \equiv 6^2 + 1 \equiv 7 \pmod{10}\)
    and the conclusion follows by induction.
ii) if $m = a6$, where 6 is an odd number larger than 1 then
\[ 2^m + 1 = (2^a)^6 + 1 \equiv 0 \pmod{(2^a + 1)} \]
and, being divisible by $2^a + 1$, is not prime;

\[ iii) \text{ since } 641 = 5 \cdot 2^7 + 1 = 5^4 + 2^4 \text{ we see that} \]
\[ 5 \cdot 2^7 \equiv -1 \pmod{641} \text{ and } 5^4 \equiv -2^4 \pmod{641}; \]
raising the first congruence to the 4th power and using the second congruence we find
\[ 5^4 \cdot 2^{28} \equiv -2^{32} \equiv 1 \pmod{641} \]
and the desired conclusion follows;

\[ \text{iv-a) since } F_0 = F_1 - 2 \text{ the proposition is} \]
true for $m = 1$; suppose true for $m$, then
\[ \prod_{n < m+1} F_n = (F_{m-2})F_m = (2^{2^m} - 1)(2^{2^m} + 1) \]
\[ = 2^{2^{m+1}} - 1 = F_{m+1} - 2 \]
and the proposition is true by induction;
6) Without loss of generality let \( n < m \); then any common factor of \( F_n \) and \( F_m \) would divide \( \prod_{j \leq m} F_j = F_m - 2 \) and, therefore, would divide 2; but \( F_n \) and \( F_m \) are odd so such a common factor may only be 1;

v) Since each \( F_n \) contains a prime factor the conclusion of (\( w-6 \)) is incompatible with the existence of only finitely many primes.

10. Without loss of generality let \( P \) be an integral polynomial with positive leading coefficient; since \( P(n) \rightarrow \infty \) with \( n \) we may choose an \( m \) such that \( P(m) > 1 \); now we note that for all \( n \), \( P(m) \) divides \( P(m + nP(m)) \) and, consequently, for infinitely many integral values of \( x \), \( P(x) \) is composite.
11. (See Luthar [1969])

i) \( p_5 = 11 > 9 = 2 \cdot 4 + 1 \) so the assertion is true for \( n = 4 \); if true for \( n \) then
\[
p_{n+1} \geq p_n + 2 > 2n + 1 + 2 = 2(n+1) + 1 \;
\]

ii) the assertion is true by checking for \( n = 1, 2, 3, 4 \); if true for \( n \), \( n \geq 4 \), then
\[
x_{n+1} = x_n + p_{n+1} > n^2 + 2n + 1 = (n+1)^2 \;
\]

iii) \( (a) \) follows from \( (i) \); for \( (b) \) we have, when \( 0 \leq j < n \), \( p_{n-j} \leq p_{n-j+1} \leq p_{n-j+2} \leq \cdots \leq p_{n+1-j} \leq 2(n + k) + 1 - 2(j + 1) \)
\[
= 2(n + k) - (2j + 1) \;
\]

for \( (c) \) note \( x_n = p_1 + \cdots + p_n \leq 2n(n + k) - (1 + 3 + 5 + \cdots + (2n-1)) = n^2 + 2nk < (n + k)^2 \);

iv) follows immediately from \( (iii) \);
v) by (iii), for each \( n \) there is a non-negative integer \( k \) such that \( (n+k)^2 \leq x_n < (n+k+1)^2 \);
when \( k = 0 \) we have \( n^2 < x_n < (n+1)^2 < x_{n+1} \),
while when \( k \neq 0 \) we have, by (iv),
\( x_n < (n+k+1)^2 = (n+k)^2 + 2(n+k) + 1 < x_n + p_{n+1} = x_{n+1} \).

12. (See Grimm [1960])

i) When \( q_k = k \), since \( k \leq n \), we have \( q_k \mid n! + k \); when \( q_k \) is a prime divisor of \( \frac{n!}{k} + 1 \) it certainly divides \( n! + k = k(\frac{n!}{k} + 1) \);

ii) case 1: \( \frac{n}{2} < k \leq n \) and \( k \) prime; then \( q_k = k \) and since \( q_k \) divides each of \( n! + j \) and \( n! \) it also divides \( j \); but \( 2 \leq j \leq n < 2k \), so \( k = j \);

case 2: \( q_k \) is a prime dividing \( k - j \) since \( k - j = k(\frac{n!}{k} + 1) - (n! + j) \); suppose now that \( q_k \leq n \); then \( q_k \mid j \), \( j = (n! + j) - n! \),
and \( q_k \mid k - j \) so \( q_k \mid k \); if \( k \leq \frac{n}{2} \) this means
\[ q_k \mid 2k \] and \( 2k \mid \frac{n}{k} \) which implies
\[ q_k \mid (\frac{n}{k} + 1) - \frac{n}{k} \] or \( q_k \mid 1 \);
thus \( \frac{n}{2} < k \leq n \) and, since we are in case 2, \( k \) is composite; again each prime factor of \( k \), including \( q_k \), divides \( \frac{n}{k} \) and hence would have
to divide 1; thus \( q_k > n \) and, since \( q_k \mid k - j \) and \( k \) and \( j \) are positive integers, not exceeding \( n \), \( k = j \);

\( \text{iii} \Rightarrow \text{iv}) \) these follow immediately from
\( \text{(i)} \Leftrightarrow \text{(ii)} \).
1. Clearly \([\alpha] \leq \alpha\); if \([\alpha] \leq \alpha - 1\) then \([\alpha] < [\alpha] + 1 \leq \alpha\) contradicting the definition of \([\alpha]\).

2. Adding the inequalities
\(\alpha + n - 1 < [\alpha + n] \leq \alpha + n, -\alpha \leq -[\alpha] < -\alpha + 1\)
yields \(n - 1 < [\alpha + n] - [\alpha] < n + 1\)
and, therefore,
\([\alpha + n] - [\alpha] = n\).

3. \(m = \left[ \frac{m}{n} \right] n + r, 0 \leq r < n\); hence
\(\frac{m + 1}{n} = \left[ \frac{m}{n} \right] + \frac{r + 1}{n} \leq \left[ \frac{m}{n} \right] + 1\).

4. \(\left[ \frac{[\alpha]}{n} \right] \leq \frac{[\alpha]}{n} \leq \frac{\alpha}{n} < \frac{[\alpha] + 1}{n} \leq \left[ \frac{\alpha}{n} \right] + 1\),
where we used \(\#3\) at the last inequality.
5. \[-\frac{1}{2} = (\alpha + \frac{1}{2}) - 1 - \alpha < [\alpha + \frac{1}{2}] - \alpha \leq (\alpha + \frac{1}{2}) - \alpha = \frac{1}{2}.\]

6. From \(-\alpha - 1 < [-\alpha] \leq -\alpha\) we see \(\alpha \leq -[-\alpha] < \alpha + 1\) and the conclusion follows.

7. \([\alpha] + [\beta] = [[\alpha] + \beta] \leq [\alpha + \beta] \leq \alpha + \beta \leq [\alpha] + [\beta] + 2\) and the conclusion follows.

8. \([\alpha + \beta] + [\alpha] + [\beta] \leq 2[\alpha] + 2[\beta] + 1 \leq [2\alpha] + [2\beta] + 1;\)

If both inequalities were equalities then \([\alpha + \beta] = [\alpha] + [\beta] + 1,\)
\([2\alpha] = 2[\alpha],\quad [2\beta] = 2[\beta],\)
but then \(2[\alpha + \beta] > [2\alpha] + [2\beta] + 1\)
\(\geq [2(\alpha + \beta)] = [(\alpha + \beta) + (\alpha + \beta)] \geq 2[\alpha + \beta]\)
which is a contradiction; hence at least one of the inequalities is a strict inequality and the conclusion follows.
9. Let \( \alpha = m + \epsilon, \beta = n + \nu \); then
\[
[\alpha][\beta] = mn \leq [\alpha \beta] = mn + [m\nu + n\epsilon + \epsilon\nu] \\
\leq mn + m + n + [\epsilon\nu] = mn + m + n \\
= [\alpha][\beta] + [\alpha] + [\beta].
\]

10. If \( \alpha = qk + r, 0 \leq r < k \), then \( q \) is the number of positive integral multiples of \( k \) not exceeding \( \alpha \); but \( \lceil \frac{\alpha}{k} \rceil = q \) so the conclusion follows.

11. By *10, \( [\alpha] - [\beta] \) is the number of positive integers \( \leq \alpha \) and not \( \leq \beta \).

12. \( [\alpha] + [-\alpha] = [[\alpha] - \alpha] \)
\[
= \begin{cases} 
0 & \text{if } \alpha \text{ is an integer;} \\
-1 & \text{otherwise.}
\end{cases}
\]

13. In *7 let \( \alpha \) and \( \beta \) both be \( \frac{\alpha}{2} \) to obtain \( 2[\frac{\alpha}{2}] \leq [\alpha] \leq [\frac{\alpha}{2}] + [\frac{\alpha}{2}] + 1 \);
\[
\text{hence } 0 \leq [\alpha] - 2[\frac{\alpha}{2}] \leq 1.
\]
14. From \( \frac{n}{2} - \frac{1}{2} < \left\lfloor \frac{n}{2} \right\rfloor \leq \frac{n}{2} \) and \( \frac{n}{2} \leq -\frac{n}{2} < \frac{n}{2} + 1 \) we find \( n - 1 < \left\lfloor \frac{n}{2} \right\rfloor - \left\lfloor -\frac{n}{2} \right\rfloor < n + 1 \), and, therefore, \( \left\lfloor \frac{n}{2} \right\rfloor - \left\lfloor -\frac{n}{2} \right\rfloor = n \).

15. \( \alpha - \frac{1}{n} < \frac{[n\alpha]}{n} \leq \alpha \) and the conclusion follows.

16. Let \( m^k \leq \lceil \alpha \rceil \leq \alpha < (m+1)^k \); then
\[
\left\lceil \frac{\alpha}{m} \right\rceil = m = \left\lfloor \frac{\alpha}{\lceil \alpha \rceil} \right\rfloor.
\]

17. Let \( \alpha = \lceil \alpha \rceil + \frac{\beta}{n} \), \( 0 \leq \beta < n \), so
\[
\left\lfloor n\alpha \right\rfloor = \left\lfloor n\lceil \alpha \rceil + \beta \right\rfloor = n\lceil \alpha \rceil + \left\lfloor \frac{\beta}{n} \right\rfloor \text{ and}
\]
\[
\left\lfloor \alpha \right\rfloor + \left\lfloor \alpha + \frac{1}{n} \right\rfloor + \cdots + \left\lfloor \alpha + \frac{n-1}{n} \right\rfloor = \sum_{j=0}^{n-1} \left\lfloor \alpha + \frac{j}{n} \right\rfloor
\]
\[
= n\lceil \alpha \rceil + \sum_{j=0}^{n-1} \left\lfloor \frac{\beta}{n} \right\rfloor = n\lceil \alpha \rceil + \sum_{j=1}^{n-1} \frac{\beta + j}{n} = n\lceil \alpha \rceil + \frac{\beta + n - 1}{n} \sum_{j=1}^{n-1} 1
\]
\[
= n\lceil \alpha \rceil + \frac{[\beta]}{n} = n\lceil \alpha \rceil + \lceil \beta \rceil.
\]

18. Put \( \frac{\alpha}{n} \) for \( \alpha \) in \# 17.

19. \( \sum_{j=0}^{n-1} \left[ m\alpha + \frac{jm}{n} \right] = \sum_{k=0}^{m-1} \sum_{j=0}^{n-1} \left[ \alpha + \frac{k}{m} + \frac{j}{n} \right]
\]
\[
= \sum_{k=0}^{m-1} \left[ n\alpha + \frac{kn}{m} \right], \text{ since}
\]
\[
\sum_{k=0}^{n-1} \left[ \alpha + \frac{k}{m} + \frac{j}{n} \right] = \left[ m \alpha + \frac{j}{n} \right] \quad \text{and}
\sum_{j=0}^{n-1} \left[ \alpha + \frac{k}{m} + \frac{j}{n} \right] = \left[ n \alpha + \frac{kn}{m} \right] \quad \text{by #17.}
\]

20. Put \( f(x) = (-1)^{[nx]} \left( \frac{n-1}{[nx]} \right) \),
\( g(x) = (-1)^{[mx]} \left( \frac{m-1}{[mx]} \right) \);
then one of \( f \), \( g \) is symmetric, the other
antisymmetric about \( x = \frac{1}{2} \); hence
\[
\int_0^1 fg = \int_0^{1/2} fg + \int_{1/2}^1 fg = \int_0^{1/2} fg + \int_0^{1/2} fg = 0.
\]

21. Let \( \mathcal{S} = \mathfrak{T}n - [\mathfrak{T}n] \); since \( \mathfrak{T}^2 = \mathfrak{T} + 1 \),
\( \mathcal{S} = \mathfrak{T}^2n - [\mathfrak{T}^2n] \); hence \(-\frac{\mathcal{S}}{\mathfrak{T}} = \mathcal{S}(1 - \mathfrak{T})\)
\[
= (\mathfrak{T}^2n - [\mathfrak{T}^2n]) - (\mathfrak{T}^2n - \mathfrak{T}[\mathfrak{T}n])
= \mathfrak{T}[\mathfrak{T}n] - [\mathfrak{T}^2n];
\]
since \( 0 < \mathcal{S} < 1 < \mathfrak{T} \), taking square brackets
yields the desired result.

22. Write \( n = q\sqrt{2} + \alpha \), \( 0 < \alpha < \sqrt{2} \),
\( q \) integral; then
a) \[(1 + \sqrt{2}) n = n + 2q + [\alpha \sqrt{2}] \] and
b) \[\left(\sqrt{2} \left(1 + \frac{1}{\sqrt{2}}\right) n + \frac{1}{2}\right)\]
\[= n + 2q + \left[\alpha (\sqrt{2} - 1) + \sqrt{2} \left[\frac{\alpha}{\sqrt{2}} + \frac{1}{2}\right]\right] ;\]
calling the last term on the right in (b) \(t\)
we see \[\left[\alpha \sqrt{2}\right] = \left[\frac{\alpha}{\sqrt{2}} + \frac{1}{2}\right]\]
\[= \begin{cases} 
[\alpha (\sqrt{2} - 1)] = 0 & \text{for } 0 < \alpha < \frac{1}{\sqrt{2}} \\
[\alpha (\sqrt{2} - 1) + \sqrt{2}] = 1 & \text{for } \frac{1}{\sqrt{2}} \leq \alpha < \sqrt{2}
\end{cases} \] = \(t\),
where, in the second case, we use
\[1 < 1 - \frac{1}{\sqrt{2}} + \sqrt{2} \leq \alpha (\sqrt{2} - 1) + \sqrt{2}\]
\[< \sqrt{2} (\sqrt{2} - 1) + \sqrt{2} = 2.\]

23. We know from § 6 (ii) that
\[u_n = \frac{1}{\sqrt{5}} \left(\tau^{n+1} - \tau'^{n+1}\right) ; \text{ further } \tau \tau' = -1 \text{ so}
\]
\[u_n = \frac{1}{\sqrt{5}} \tau^{n+1} + \frac{(-1)^n}{\sqrt{5}} \tau'^{n+1} = \left[\frac{1}{\sqrt{5}} \tau^{n+1} + \frac{1}{2}\right] ,\]
since \[\frac{1}{\sqrt{5}} \tau^{n+1} < \frac{1}{2} .\]

24. Among 1, 2, \cdots, n there are \(\left[\frac{n}{p}\right]\) divisible by \(p\),
and, of these, there are \(\left[\frac{n}{p^2}\right] = \left[\frac{n}{p^2}\right]\) divisible by \(p^2\), etc; thus the highest power of \(p\) in \(n!\) is as stated.
25. i) \( \left( \frac{m}{n} \right) \frac{m!}{(m-n)! n!} \) so the highest power of \( p \) in \( \left( \frac{m}{n} \right) \) is

\[
\sum_{j=1}^{\infty} \left\{ \left[ \frac{m}{p^j} \right] - \left[ \frac{m-n}{p^j} \right] - \left[ \frac{n}{p^j} \right] \right\} \geq 0
\]

since, by *7*, each term is \( \geq 0 \); since this is true for every prime \( p \) the conclusion follows;

ii) this follows exactly as does (i) if one uses the obvious extension of *7*;

iii) this follows in a similar way using *8*.

26. \( \left[ \frac{n}{m} \right] - \left[ \frac{n-1}{m} \right] = \begin{cases} 1 & \text{if } m \text{ divides } n \\ 0 & \text{otherwise} \end{cases} \)

thus the sum is \( \geq \) the number of positive integer divisors of \( n \) and this number is 2 precisely when \( n \) is prime.

27. \( \sum_{k=2}^{n} \left[ \frac{n/k}{n/k} \right] \geq 2 \) for \( n \geq 2 \), \( n \) not prime;

for \( n \) prime this sum is 1;
thus for each composite $n$ the summand is 0 while for each prime $n$ the summand is 1.

28. For $x$ irrational $[\cos^2 m! \pi x] = 0$ while for $x$ rational, say $\frac{\xi}{t}$, all terms with $m \geq t$ have value 1.

29. $xy \leq n$ is equivalent, under the conditions of the system, to $x \leq \frac{n}{y}$ and, for fixed $y$, the number of such $x$ is $[\frac{n}{y}]$; now allow $y$ to vary over $1, 2, \ldots, n$; this yields the left equality; for the right equality note that the number of lattice points on the vertical line through $k$ and beneath the curve is $[\frac{n}{k}]$; the number in the shaded region is twice the number in the doubly shaded region diminished by the number in the triply shaded region.
30. Suppose \(2x = qb + r, 0 \leq r < b\);

i) if \(q\) is even, say \(q = 2s\), then
\[0 \leq x - sb = \frac{r}{b} < \frac{b}{2},\]
while if \(0 \leq x - sb < \frac{b}{2}\) then
\[
\left\lfloor \frac{2x}{b} \right\rfloor = \left\lfloor 2s + \frac{1}{2} \right\rfloor = 2s \text{ is even};
\]

ii) if \(q\) is odd, say \(q = 2s + 1\), then
\[0 \leq x - (s+1)b \text{ and } -\frac{b}{2} < x - (s+1)b < 0,\]
while if \(-\frac{b}{2} < x - (s+1)b < 0\) then \(-1 < \frac{2x}{b} < -2s - 2 < 0\), so
\[0 < \frac{2x}{b} - 2s - 1 < 1 \text{ and } \left\lfloor \frac{2x}{b} \right\rfloor \text{ is odd.}\]

31. i) \(\left\lfloor \frac{an}{b} \right\rfloor\) is the number of lattice points on the half open segment \((A,B)\) in the diagram; when \(d = 1\) there are no such lattice points on \(OC\) and, in general, there are \(d - 1\) such points on \(OC\); thus the indicated sum is half the number of lattice points inside the rectangle \(OBCa\) plus \(\frac{d-1}{2}\).
ii) the left hand side is exactly the number of lattice points in the indicated rectangle.

32. i) From \(ax+by = k = akx_0 + bky_0\) we see that \(a(x-kx_0) = b(ky_0-y)\);
    since \((a,b) = 1\) this means there is a \(t\) such that \(x-kx_0 = tb\), \(ky_0-y = ta\);

ii) from (i) if \(x, y\) is non-negative we must have \(kx_0 + bt \geq 0\) and \(ky_0 - at \geq 0\);
    i.e. \(-\frac{kx_0}{b} \leq t \leq \frac{ky_0}{a}\) so the number of such solutions is \(1 + \left\lfloor \frac{ky_0}{a} \right\rfloor + \left\lfloor \frac{kx_0}{b} \right\rfloor\);

iii) if \(k\) has the stated form then
    
    \[1 + \left\lfloor \frac{kx_0}{b} \right\rfloor + \left\lfloor \frac{ky_0}{a} \right\rfloor =
    \]
    \[1 + \left\lfloor \frac{r}{b} - ry_0 + sx_0 - ax_0 \right\rfloor + \left\lfloor \frac{s}{a} - sx_0 + ry_0 - by_0 \right\rfloor = 0;
    \]
on the other hand, if (*) has no non-negative solution, then for suitable \( r, s, 0 \leq r < b, 0 \leq s < a, \)
\[ \begin{align*}
0 \leq \left[ \frac{r}{ab} \right] \leq 1 + \left[ \frac{k}{b} \right] + \left[ \frac{y_0}{a} \right] = 1 + \frac{k}{b} + \frac{y_0}{a} = \frac{k + ab - ar - bs}{ab} = 0,
\end{align*} \]
which can happen only when \( k = ar + bs - ab; \)

\\( \text{iv)} \) the 2\textsuperscript{nd} assertion follows from (iii) by observing that \( ab - a - b = a(b-1) + b(a-1) - ab; \)
when \( k > ab - a - b \) we observe that
\[ \begin{align*}
1 + \left[ \frac{k}{b} \right] + \left[ \frac{y_0}{a} \right] = \frac{k + ab - ar - bs}{ab} > \frac{2ab - a(1+r) - b(1+s)}{ab} \\
> 0 \quad \text{and the conclusion follows from (ii)};
\end{align*} \]

\\( \text{v)} \) we need to count the number of distinct non-negative \( ar + bs - ab, 0 \leq r < b, 0 \leq s < a; \) if \( ar + bs - ab = ar' + bs' - ab \)
then \( a(r - r') = b(s' - s) \) and, since \( (a, b) = 1, \)
this means \( r = r', s = s' \); thus they are all distinct so we need only determine how many
are non-negative;
put \( r = b - i \), \( s = a - j \), \( 1 \leq i \leq b \), \( 1 \leq j \leq a \) and examine

\[
a(b-i) + b(a-j) \geq ab
\]
or, what is the same, \( ab \geq ai + bj \); for fixed \( i \) we have \( \lceil a - \frac{a}{b} i \rceil \) values of \( j \) so altogether we have

\[
\sum_{i=1}^{b} \left( a - \frac{a}{b} i \right) = ab + \sum_{i=1}^{b} \left( -\frac{a}{b} i \right) = ab - a + \sum_{i=1}^{b-1} \left( -1 - \left\lceil \frac{a}{b} i \right\rceil \right)
\]

\[
= ab - a - (b-1) - \frac{(a-1)(b-1)}{2} = \frac{(a-1)(b-1)}{2},
\]

where we have used \( = 31 (i) \).
Kronecker Theorems - Solutions

1. i) By IV #1, \(0 \leq n\alpha - [n\alpha] < 1\) and, since \(\alpha\) is irrational, the 1st inequality is strict;

ii) \(P_n - P_m = (n - m)\alpha - [n\alpha] + [m\alpha]\) and, if this were 0, \(\alpha\) would be rational contrary to fact;

iii) \(P_1, \ldots, P_{m+1}\) are pairwise distinct numbers between 0 and 1; thus some pair of them must be within \(\frac{1}{m}\) of each other; taking \(\frac{1}{m} < \epsilon\) yields the desired result;

iv) \(P_r = P_{n+r} - P_n + [n\alpha + r\alpha] - [n\alpha] - [r\alpha]\); consequently when \(|P_{n+r} - P_n| < \epsilon\) then since \(0 < P_r < 1\) and \(P_r\) is within \(P_{n+r} - P_n\) of an integer, either \(P_r > 1 - \epsilon\) or \(P_r < \epsilon\);
v) for \( r \) as in (w) the points \( P_r, P_{2r}, \ldots, P_{sr} \), where \( s > \frac{1}{e} \), constitute an \( e \)-dense set of points (i.e. every point in the unit interval is within \( e \) of one of these points); the union of such sets for \( e = 1, \frac{1}{2}, \frac{1}{3}, \ldots \) is contained in \( \{ P_1, P_2, \ldots \} \) and, therefore, this set is dense.

2. i) If \( P_n \neq P_m, n \neq m \), then
\[
(n\alpha) = (m\alpha) \text{ and } (n\beta) = (m\beta)
\]
which contradicts \# 1 (ii) ;

ii) let \( Q = (q_1, q_2) \); then \( P_m Q = P_n P_{n+r} \) implies \( q_1 = \{ m\alpha - [m\alpha] \} + \{ n\alpha + r\alpha - [n\alpha + r\alpha] \} - \{ n\alpha - [n\alpha] \} \) and a similar expression for \( q_2 \); thus
\[
f(Q) = \left( ((m+r)\alpha), ((m+r)\beta) \right) = P_{m+r} ;
\]
iii) let $Q = (q_1, q_2)$; then the given equality implies

$$q_1 = \alpha - [\alpha] + m \{ \alpha + r\alpha - [\alpha + r\alpha] - \alpha + [\alpha] \}$$

$$+ n \{ \alpha + s\alpha - [\alpha + s\alpha] - \alpha + [\alpha] \}$$

and a similar expression for $q_2$; thus

$$f(Q) = ((\alpha + mr\alpha + ns\alpha), (\beta + mr\beta + ns\beta))$$

$$= P_{1+mr+ns};$$

iv) as $m$ and $n$ run over the non-negative integers the points $Q$ such that

$$P_1Q = mP_1P_{1+r} + nP_1P_{1+s}$$

have $f$ images that are $L$-dense in the unit square; but these $f(Q)$ are just the $P_{1+mr+ns}$. 

3. i) If $\alpha = \frac{a}{b}$ then $6\alpha + 0.\beta - a = 0$ for $ab \neq 0$; similarly for $\beta$ ;
ii) by \( \star_2 (i) \) all \( P_n \) are distinct; since they all lie in the unit square they must possess an accumulation point; consequently, there are points of the set arbitrarily close together;

iii) there is some vector \( P_1 Q = P_n P_{n+r} \) with \( |P_n P_{n+r}| < \varepsilon \); thus we know \( Q \) is in the unit square; using \( \star_2 (ii) \), \( f(Q) = P_{i+r} = f(P_{i+r}) \) and we are done since \( f \) is one to one on the unit square;

w) this follows immediately from (ii)\&(iii);

v) if \( P_1 P_{i+r} \) is parallel to \( P_1 P_{i+s} \) then the triangle determined by \( P_1, P_{i+r}, P_{i+s} \) has zero area so

\[
\begin{vmatrix}
(\alpha) & (\beta) & 1 \\
(\alpha+ra) & (\beta+r\beta) & 1 \\
(\alpha+sa) & (\beta+s\beta) & 1
\end{vmatrix} = \begin{vmatrix}
\alpha & \beta & 1 \\
[\alpha]-[\alpha+ra] & [\beta]-[\beta+r\beta] & -r \\
[\alpha]-[\alpha+sa] & [\beta]-[\beta+s\beta] & -s
\end{vmatrix}
\]
in the expansion on the right the coefficient of \( \alpha \) must be 0, i.e.
\[
\frac{[\beta] - [\beta + r\beta]}{r} = \frac{[\beta] - [\beta + s\beta]}{s};
\]
if this happened for infinitely many \( s \), then since as \( s \to \infty \) the right side tends to \( \beta \),
\[
\frac{[\beta] - [\beta + r\beta]}{r} = \beta
\]
which contradicts (i);

vi) by (iv), (v) and \#2(iv) there is an \( \varepsilon \)-dense set of \( P_n \) for each \( \varepsilon > 0 \); therefore the \( P_n \) are dense.
vi Beatty, Skolem Theorems ~ Solutions

1. If $0 < \alpha < 1$ then given $n$ there is an $m$ such that $m\alpha - 1 < n \leq m\alpha$; hence $[m\alpha] = n$.

2. Each of $A(\alpha)$ and $A(\beta)$ contains infinitely many positive integers; if $0 < \alpha \leq 1$ or $0 < \beta \leq 1$ then $A(\alpha) \cap A(\beta)$ is $A(\alpha)$ or $A(\beta)$ and, therefore, is not empty; thus each of $\alpha, \beta$ is $> 1$.

3. $[n\alpha] = [nm\frac{\alpha}{m}]$.

4. 1 is in $A(\sqrt{2})$ but 1 is not in $A(1 + \sqrt{2})$; that $A(1 + \sqrt{2}) \subset A(\sqrt{2})$ is the content of IV*22.

5. If $\alpha = \frac{a}{b}$ and $\beta = \frac{c}{d}$ then $[nbc\alpha] = [nda\beta]$ for all $n$. 
6. Since \( \alpha > 1 \) and \( \beta > 1 \) each of \( S(\alpha) \), \( S(\beta) \) is a sequence of distinct terms; the total number of terms not exceeding \( n \) taken together is 
\[ \left[ \frac{n}{\alpha} \right] + \left[ \frac{n}{\beta} \right] \]; from \( 0 < \frac{n}{\alpha} - \left[ \frac{n}{\alpha} \right] < 1 \) and \( 0 < \frac{n}{\beta} - \left[ \frac{n}{\beta} \right] < 1 \) we have \( 0 < n - \left[ \frac{n}{\alpha} \right] - \left[ \frac{n}{\beta} \right] < 2 \) and, therefore, 
\[ \left[ \frac{n}{\alpha} \right] + \left[ \frac{n}{\beta} \right] = n - 1 \]; hence the total number of terms not exceeding \( n \) in \( S(\alpha) \) and \( S(\beta) \) is \( n - 1 \); since this is true for each \( n \geq 1 \) each interval \( n \) to \( n + 1 \) contains exactly one such term; this implies 
\[ A(\alpha) \cup A(\beta) = \mathbb{Z} \text{ and } A(\alpha) \cap A(\beta) = \emptyset \]
which yields the desired conclusion.

7. This follows immediately from #6 since 
\[ \frac{1}{\sqrt{2}} + \frac{1}{2 + \sqrt{2}} = 1. \]

8. This follows immediately from #6 since 
\[ \frac{1}{3} + \frac{1}{1/2} = 1. \]
9. As \( n \) runs over the positive integers the sequences \( \{ \tau n \} \) and \( \{ \tau^2 n \} \) run disjointly over these integers; thus the sequences \( \{ \tau [\tau n] \} \), \( \{ \tau [\tau^2 n] \} \) run disjointly over all positive integral multiples of \( \tau \); therefore the 1st two sequences yield \( \{ [\tau n] \} \) and this with \( \{ [\tau^2 n] \} \) disjointly exhausts the positive integers.

10. Put \( B_0 = \{ [\tau^2 n] \mid n \in \mathbb{Z} \} \), \( B_{m+1} = \{ [\tau^2 n] \mid n \in B_m \} \) for \( m \geq 0 \); then \( B_{m+1} \subseteq B_m \) for \( m \geq 0 \) and by *8, \( A_0 \cup B_0 = \mathbb{Z} \) and \( A_{m+1} \cup B_{m+1} = B_m \); thus each \( A_j \subseteq B_m \) for \( m < j \); thus \( A_j \cap A_m = \emptyset \) for \( m < j \) since for such \( m \), \( A_m \cap B_m = \emptyset \); now \( A_{m+1} = B_m \setminus B_{m+1} \) so

\[ \bigcup_{j \geq 1} A_j = \bigcup_{j \geq 1} (B_{j-1} \setminus B_j) = B_0 \quad \text{and} \quad \bigcup_{j \geq 0} A_j = A_0 \cup B_0 = \mathbb{Z} \; ; \]

a picture to go with the argument is:

\[ \{ [\tau n] \}, \{ [\tau^2 [\tau n]] \}, \{ [\tau^2 [\tau^2 [\tau n]]] \}, \ldots \]

\[ \{ [\tau^2 n] \}, \{ [\tau^2 [\tau^2 n]] \}, \{ [\tau^2 [\tau^2 [\tau^2 n]]] \}, \ldots \]
11. The proof is the same as that given for *10.

12. Since $A(\alpha) \cap A(\beta)$ is finite $\frac{[\frac{\alpha}{n}]}{n} + [\frac{\beta}{\delta}] \to 1$; but, by IV *15, this quantity tends to $\frac{1}{\alpha} + \frac{1}{\beta}$.

13. Immediate from *5, 6 and 12.

14. From *6 and 12.

15. i) Since 1 is in exactly one of the sequences, it must be in $S(\alpha_1)$; thus since $\alpha_1 > 1$ (not all positive integers are in $S(\alpha_1)$) we must have $\alpha_1 = 1 + \delta$, $0 < \delta < 1$;

ii) this follows from

$$[ (k+1)\alpha_1 ] - [ k\alpha_1 ] \leq (k+1)\alpha_1 - (k\alpha_1 - 1) = \alpha_1 + 1 = 2 + \delta < 3$$

iii) suppose $(j-1)\delta < 1 \leq j\delta$; then for $i \leq j-1$ we have $[ i\alpha_1 ] = i + [i\delta] = i$ so $i$ is in $S(\alpha_1)$ and
\[ j \alpha_1 = j + [ j \delta ] \geq j + 1 \text{ so } j \text{ is not in } S(\alpha_1); \]

w) since \( \alpha_2 < \cdots < \alpha_n \) it is clear that if \( m \neq \lfloor \alpha_2 \rfloor \) then \( \lfloor \alpha_2 \rfloor \) is an integer smaller than \( m \) and must then be in \( S(\alpha_1) \) in violation of the disjointness of \( S(\alpha_1) \) and \( S(\alpha_2) \); thus \( \alpha_2 = m + \epsilon, 0 \leq \epsilon < 1 \);

v) since \( x \) is not in \( S(\alpha_1) \) there is a \( k \) such that \( x = \lfloor k \alpha_1 \rfloor + 1 \) and \( \lfloor (k+1) \alpha_1 \rfloor - \lfloor k \alpha_1 \rfloor > 1; \) this implies \( \lfloor (k+1) \delta \rfloor > \lfloor k \delta \rfloor \) and the existence of an integer \( t \) such that \( k \delta < t \leq (k+1) \delta \); since \( \delta < 1 \), \( \lfloor k \delta \rfloor = t-1 \) and \( x = k+1 + \lfloor k \delta \rfloor = k + t; \) further, \( k \delta < t \leq (k+1) \delta < \cdots < (k+m-1) \delta < k \delta + 1 < (k+m) \delta < (k+m+1) \delta \)

and \( t+1 \) either lies, Case 1, between the 3rd last and 2nd last terms or, Case 2, between the last two terms;
Case 1: \( t+1 \leq (k+m)\delta \) : then
\[
[(k+m)\alpha_1] = k+m+t+1 \text{ and } [(k+m-1)\alpha_1] = k+m+t-1;
\]
thus \( k+m+t \) is not in \( S(\alpha_1) \);

Case 2: \( t+1 > (k+m)\delta \) : then
\[
[(k+m+1)\alpha_1] = k+m+t+2 \text{ and } [(k+m)\alpha_1] = k+m+t;
\]
thus \( k+m+t+1 \) is not in \( S(\alpha_1) \);

since
\[
[(k+j)\alpha_1] = k+j + [(k+j)\delta] = k+j+t
\]
for \( 1 \leq j \leq m-1 \) we conclude that the next term after \( x \) missing from \( S(\alpha_1) \) is either \( x+m \) or \( x+m+1 \);

vi) \( \alpha_2 = m+\epsilon \) so \( [n\alpha_2] = nm + [n\epsilon] \) and
\[
[(n+1)\alpha_2] = (n+1)m + [(n+1)\epsilon] = \ [n\alpha_2] + m + [(n+1)\epsilon] - [n\epsilon]
\]
and this last quantity is either \( [n\alpha_2] + m \) or \( [n\alpha_2] + m + 1 \);
vii) the 1st integer missing from \( S(\alpha_1) \) is \( m \) which is also the 1st element of \( S(\alpha_2) \); suppose now that the proposition is true up to \( k \); thus if \( x_k \) is the \( k \text{th} \) positive integer missing from \( S(\alpha_1) \) then \( x_k \) is also the \( k \text{th} \) element of \( S(\alpha_2) \); by earlier results
\[
x_{k+1} = x_k + m \text{ or } x_k + m + 1
\]
and \( \lfloor (k+1)\alpha_2 \rfloor = \lfloor k\alpha_2 \rfloor + m \text{ or } \lfloor k\alpha_2 \rfloor + m + 1 \),
since \( \lfloor k\alpha_2 \rfloor = x_k \) this means
\[
\lfloor (k+1)\alpha_2 \rfloor = x_k + m \text{ or } x_k + m + 1 ;
\]
whichever value \( x_{k+1} \) assumes, the other, by (vii), must be in \( S(\alpha_1) \) and thus not be in \( S(\alpha_2) \); consequently \( x_{k+1} = \lfloor (k+1)\alpha_2 \rfloor \) and the induction is complete;

viii) by (vii) all integers are in either \( S(\alpha_1) \) or \( S(\alpha_2) \) so \( S(\alpha_3) = \emptyset \) contrary to assumption.
16. i) \[ [a \alpha \beta] = [-b \alpha \alpha] \ ; \]

ii) the point \((1, 1)\) is on the line \(ax + by = a + b\) and the slope of this line is \(-\frac{a}{b}\) and this quantity is \(\geq 0\); every line of positive slope passing through \((1, 1)\) goes through \(S\);

iii) since \(a(1 - \frac{1}{\alpha}) + b(1 - \frac{1}{\beta}) < a + b - 1 < a + b\) the points \((1 - \frac{1}{\alpha}, 1 - \frac{1}{\beta})\) and \((1, 1)\) are on opposite sides of \(ax + by = a + b - 1\) and, therefore, this line must pass through \(S\).

17. i) By \(\not= S\) there are positive integers \(x, y\) such that \(ax - by = d\); consequently there are integers \(u, v\) such that \(au + bv = -cd\); this yields \(au + bv = -a \frac{d}{\alpha} - b \frac{d}{\beta}\);

ii) \(\frac{d}{b} (u + \frac{d}{\alpha})\) is irrational so the \(w_n\) are dense in the unit interval (see \(\not= 1(v)\)); thus
the \( x_n \) are dense in the interval \( [0, \frac{b}{d}] \), the
\( y_n \) are dense in the interval \( [0, -\frac{a}{d}] \), and the
\((x_n, y_n)\) all lie on the line with slope \(-\frac{a}{b}\)
passing through the origin; the conclusion follows;

(iii) this follows immediately from the facts
that \((c, d) = (a, b, c) = 1 = (\frac{a}{d}, \frac{b}{d})\);

(iv) immediate upon substitution and the
use of \(\frac{a}{\alpha} + \frac{b}{\beta} = c\) along with the equalities in
(iii) and the values of \(x_n, y_n\) given in (ii);

(v) by (ii), for each fixed \( m \) the points
\((x_{nm}, y_{nm})\) are dense on the line segment
joining \((\frac{mb}{d} + u_1 + \frac{s}{\alpha}, -\frac{ma}{d} + v_1 + \frac{s}{\beta})\)
and \((\frac{(m+1)b}{d} + u_1 + \frac{s}{\alpha}, -\frac{(m+1)a}{d} + v_1 + \frac{s}{\beta})\);

varying \( m \) over all the integers yields the
desired result;
vi) taking \( g = a + b \) and \( g = a + b - 1 \), respectively, this follows from (v) and \#16 (ii) in the 1st case and from (v) and \#16 (iii) in the 2nd case;

\[ \text{vi}) \text{ if } b < 0, c = 0 \text{ this was proved in } \#16 (i) \text{; otherwise, by (vi), infinitely many } (x_{nm}, y_{nm}) \text{ lie in } S; \text{ if } (x_{nm}, y_{nm}) \text{ is in the interior of } S \text{ then} \]
\[ 1 - \frac{1}{\alpha} < x_n + \frac{mb}{d} + u_1 + \frac{s}{\alpha} = nu + \frac{nd}{\alpha} - \frac{b}{d} \left[ \frac{nd}{b}(u + \frac{d}{\alpha}) \right] + u_1 + \frac{s}{\alpha} \]
\[ = \frac{nd + s}{\alpha} + u_2 < 1, \]
\[ 1 - \frac{1}{\beta} < y_n - \frac{ma}{d} + v_1 + \frac{r}{\beta} = -na(u + \frac{d}{\alpha}) + a \left[ \frac{nd}{b}(u + \frac{d}{\alpha}) \right] + v_1 + \frac{s}{\beta} \]
\[ = \frac{nd + s}{\beta} + v_2 < 1, \]

where \( u_2, v_2 \) are integers and we have used (i) at the last equality in the 2nd line; these inequalities yield
\[ nd + s < (1 - u_2) \alpha < nd + s + 1, \]
\[ nd + s < (1 - v_2) \beta < nd + s + 1 \]
from which we conclude
\[ [(1 - u_2) \alpha] = nd + s = [(1 - v_2) \beta] \]
and, therefore, that \( A(\alpha) \cap A(\beta) \neq \emptyset \).
18. By Kronecker's theorem in 2 dimensions, see V #3 (vi), there are integers \( n \) such that
\[
0 < \frac{n}{\alpha} - \left\lfloor \frac{n}{\alpha} \right\rfloor < \frac{1}{\alpha}, \quad 0 < \frac{n}{\beta} - \left\lfloor \frac{n}{\beta} \right\rfloor < \frac{1}{\beta};
\]
thus \( 0 < n - \left\lfloor \frac{n}{\alpha} \right\rfloor \alpha < 1 \) and \( 0 < n - \left\lfloor \frac{n}{\beta} \right\rfloor \beta < 1 \) so
\[
\left\lfloor \frac{n}{\alpha} \right\rfloor \alpha = \left\lfloor \frac{n}{\beta} \right\rfloor \beta.
\]

19. If \( \frac{a}{\alpha} + \frac{b}{\beta} = 1 \) then by Beatty's theorem, see #6, \( A(\frac{a}{\alpha}) \cap A(\frac{b}{\beta}) = \emptyset \); since, by #3,
\[
A(\alpha) \subseteq A(\frac{a}{\alpha}) \text{ and } A(\beta) \subseteq A(\frac{b}{\beta})
\]
we conclude \( A(\alpha) \cap A(\beta) = \emptyset \) and the sufficiency of the stated conditions is proved;
on the other hand if \( A(\alpha) \cap A(\beta) = \emptyset \) then by #18 it is not true that \( 1, \frac{1}{\alpha}, \frac{1}{\beta} \) are rationally independent while from #17 it is clear that they cannot be dependent unless
\[
a > 0, \; b > 0, \; c = 1.
\]
20. If the theorem were false then by \#19 there are positive integers \(a, b, c, d, e, f\) such that
\[
\frac{a}{\alpha} + \frac{b}{\beta} = 1, \quad \frac{c}{\alpha} + \frac{d}{\delta} = 1, \quad \frac{e}{\beta} + \frac{f}{\delta} = 1;
\]
thus
\[
\frac{ae}{\alpha} + \frac{be}{\beta} = e, \quad \frac{ace}{\alpha} - \frac{bcf}{\delta} = ce - cb,
\]
\[
\frac{be}{\beta} + \frac{bf}{\delta} = b, \quad \frac{ace}{\alpha} + \frac{ade}{\delta} = ae,
\]
\[
\frac{ae}{\alpha} - \frac{bf}{\delta} = e - b, \quad \frac{bcf}{\delta} + ade = ae - ce + cb;
\]
this means that \(\delta\), and, therefore, also \(\alpha\) are rational; but then, by \#5,
\[
A(\alpha) \cap A(\beta) \neq \emptyset.
\]

21. The line passing through the 2 given points is \(\frac{x}{\alpha} + \frac{y}{\delta} = 1\); the conclusion now follows from \#19.
The Game of Wythoff - Solutions

1. Direct calculation shows this for the first pair and also shows that any B move from any other pair enables A to follow with a move to an earlier pair or to an immediate win.

2. Assume \( \{a, b\} \) is not in the list and \( a < b, a < 12 \); now \( a \) occurs in some pair \( \#_1 \) and either \( \{a, s\}, a < s \), is there or \( \{s, a\}, s < a \), is there; when \( \{a, s\}, a < s \), is there then

   - if \( b > s \) the desired move is \( \{a, b\} \rightarrow \{a, s\} \);
   - if \( b < s \) the desired move is \( \{a, b\} \rightarrow \{c, d\} \), where \( b - a = d - c \);

   when \( \{s, a\}, s < a \), is there the desired move is \( \{a, b\} \rightarrow \{a, s\} \).
3. By #1 it is clear that \( \{m, n\} \) must not be in the list if \( A \) can force a win for himself; note now that there is always a move \( A \) can make which leaves to \( B \) one of the sets on the list.

4. The \( n^{th} \) element of the desired list is \( \{a, b\} \), \( a < b \), where \( b - a = n \) and \( a \) is the smallest positive integer not appearing in the \( 1^{st} \) \( n - 1 \) sets; now follow the proofs given in #2, 3.

5. Since \( \frac{1}{c} + \frac{1}{c^2} = 1 \) each positive integer occurs precisely once among the numbers \( [n c], [n c^2], n \geq 1 \), as was proved in vi #8 as a consequence of Beatty's theorem (see vi #6); further,

\[
[n c^2] - [n c] = [n (c+1)] - [n c] = n.
\]
\textbf{viii $\tau, \sigma, \varphi$ - Solutions}

1. i) Each divisor of $ab$ is of the form $a^d b^e$, where $d$ divides $a$ and $e$ divides $b$; further if either $d \neq d_1$ or $e \neq e_1$ then $d e \neq d_1 e_1$ since $(a, b) = 1$; thus since the number of possible $d$'s is $\tau(a)$ and the number of possible $e$'s is $\tau(b)$ the number of divisors of $ab$ is just $\tau(a) \tau(b)$; one may write the above argument as follows: $\tau(ab) = \sum_{d \mid a} \sum_{e \mid b} 1 = \left( \sum_{d \mid a} 1 \right) \left( \sum_{e \mid b} 1 \right) = \tau(a) \tau(b)$;

ii) if $\sigma(a) = a_1 + \cdots + a_s$, $\sigma(b) = b_1 + \cdots + b_t$ then $\sigma(ab) = \sum_{i,j} a_i b_j = (a_1 + \cdots + a_s)(b_1 + \cdots + b_t) = \sigma(a) \sigma(b)$, where no divisor of $ab$ is counted twice because $(a, b) = 1$;

iii) a number $m$ is prime to $ab$ if and only if it is prime to each of $a$ and $b$ (recall
\[(a, b) = 1\); thus \(1 \leq s < a, 1 \leq t < b\), is
prime to \(ab\) only if \((s, a) = 1\) and \((t, b) = 1\); thus the number of pairs is just \(\varphi(a) \varphi(b)\).

2. i) The divisors of \(p^\alpha\) are exactly
\(1, p, p^2, \ldots, p^\alpha\) so \(T(p^\alpha) = \alpha + 1\);

ii) by (i) we see that
\[\sigma(p^\alpha) = 1 + p + \cdots + p^\alpha = \frac{p^{\alpha+1} - 1}{p - 1};\]

iii) all numbers except the multiples of \(p\) are prime to \(p^\alpha\) so
\[\varphi(p^\alpha) = p^\alpha - \frac{p^\alpha}{p} = p^\alpha (1 - \frac{1}{p}).\]

3. By an induction argument each of the results of \#1 may be extended to a product
of \(k\) pairwise relatively prime factors. Thus:

i) \(T(n) = T(p_1^{\alpha_1}) \cdots T(p_k^{\alpha_k})
= (\alpha_1 + 1) \cdots (\alpha_k + 1);\)
\[ \sigma(n) = \sigma(p_1^{\alpha_1}) \cdots \sigma(p_k^{\alpha_k}) = \prod_{j=1}^{k} \frac{p_j^{\alpha_j+1} - 1}{p_j - 1}; \]

\[ \varphi(n) = \varphi(p_1^{\alpha_1}) \cdots \varphi(p_k^{\alpha_k}) = n \prod_{p|n} (1 - \frac{1}{p}); \]

4. If \( \tau(n) \) is odd and \( n \) is as in #3 then all \( \alpha \) are even; consequently \( n \) is a square.

5. As \( d \) runs over the divisors of \( n \) so also does \( \frac{n}{d} \); thus \( \prod_{d|n} \frac{n}{d} = \prod_{d|n} \frac{n}{d} = n^{\tau(n)} \prod_{d|n} \frac{1}{d} \) and, therefore, \( (\prod_{d|n} d)^2 = n^{\tau(n)} \) from which the desired result is immediate.

6. If \( \delta \mid n \) then \( 2^{\delta-1} \mid 2^n - 1 \) and the result follows.

7. If \( \delta \) is an odd divisor of \( n \) then \( 2^{\frac{n}{\delta} + 1} \mid 2^n + 1 \); however the divisor 1 of \( 2^n + 1 \) does not correspond to any divisor of \( n \).
8. Let \( n = n_1, \ldots, n_k \), where \( n_j = p_1^\alpha_1 \ldots p_k^\alpha_k \); then
\[
\sum_{d \mid n} \tau^3(d) = \sum_{j=1}^k a_j \ln j \ldots \ln k \sum_{a_1, \ldots, a_k \mid n_k} \tau^3(a_1) \ldots \tau^3(a_k) = \prod_{j=1}^k (\tau^3(a_j) = \prod_{j=1}^k (1^3 + \ldots + (\alpha_j + 1)^3)) = (\sum_{d \mid n} \tau(d))^2.
\]

9. For each \( j \) there are \( \tau(j) \) pairs \( x, y \) such that \( xy = j \). Hence there are \( \tau(1) + \ldots + \tau(n) \) pairs \( x, y \) such that \( xy \leq n \). For each \( j \) there are \( \left[ \frac{n}{j} \right] \) values of \( x \) such that \( xj \leq n \). Hence there are \( \left[ \frac{n}{1} \right] + \ldots + \left[ \frac{n}{n} \right] \) pairs \( x, y \) such that \( xy \leq n \). Now this last sum is just the number of lattice points in the first quadrant under the curve \( xy = n \). That number is twice the number in the shaded region diminished by the number in the doubly shaded region.
10. The argument is the same as that given for \( \sigma_3(a) \).

11. \( a \sigma(a) \sigma(b) < \sigma(ab) \) since \( a \) contributes to the right but not to the left; hence \( \frac{\sigma(a)}{a} < \frac{\sigma(ab)}{ab} \); clearly \( \sigma(ab) \leq \sigma(a) \sigma(b) \) since every divisor of \( ab \) will appear on the right and some of them may appear more than once; consequently the right inequality follows.

12. If \( a = p^{\alpha} \), \( b = p^{\alpha + \beta} \) then \( (a, b) = p^\alpha \) and \( \sigma(a) \sigma(b) = \frac{p^{\alpha + 1}}{p - 1} \cdot \frac{p^{\alpha + \beta + 1} - 1}{p - 1} \) and \( \sum_{d | (a, b)} \sigma \left( \frac{ab}{d^2} \right) = \sum_{j=0}^{\alpha} p^j \sigma \left( p^{2 \alpha + \beta - 2j} \right) = \sum_{j=0}^{\alpha} p^j \frac{p^{2 \alpha + \beta - 2j + 1} - 1}{p - 1} \)

\[ \frac{1}{p - 1} \left\{ \sum_{j=0}^{\alpha} p^{\alpha + \beta + 1} - \sum_{j=0}^{\alpha} p^{\alpha - j} \right\} = \frac{p^{\alpha + 1} - 1}{p - 1} \cdot \frac{p^{\alpha + \beta + 1} - 1}{p - 1} \]

\( \sigma(a) \sigma(b) \);

If \( a = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \), \( b = p_1^{\beta_1} \cdots p_k^{\beta_k} \) then \( \sigma(a) \sigma(b) = \prod_{j=1}^{k} \sigma(p_j) \sigma(p_j^{\beta_j}) = \prod_{j=1}^{k} \sum_{d | (p_j^{\alpha_j}, p_j^{\beta_j})} \sigma \left( \frac{p_j^{\alpha_j} p_j^{\beta_j}}{d^2} \right) \sum_{d | (a, b)} \sigma \left( \frac{ab}{d^2} \right) \left( \frac{a b}{d^2} \right) \)
13. \[ \sigma(1) + \cdots + \sigma(n) = \sum_{d=1}^{n} d \sum_{\substack{\ell \leq n \, \ell \mid d}} 1 = \sum_{d=1}^{n} d \left\lfloor \frac{n}{d} \right\rfloor. \]

15. i) \[ \varphi(n^2) = n^2 \prod_{p \mid n^2} \left( 1 - \frac{1}{p} \right) = n^2 \prod_{p \mid n} \left( 1 - \frac{1}{p} \right) = n \varphi(n); \]

ii) since \( n \geq 2 \), \( n \) does not contribute to \( \varphi(n) \) so \( \varphi(n) < n; \)

iii) \[ \varphi(n^2) + \varphi((n+1)^2) = n \varphi(n) + (n+1) \varphi(n+1) \leq n(n-1) + (n+1)n = 2n^2, \text{ with equality only if } n \text{ and } n+1 \text{ are primes, which cannot happen with } n \geq 3. \text{ (For generalizations see the solution to Luther [1972].)} \]

16. This follows from the fact that \( (m,n) = (n-m,n). \)
17. Let \( n = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \) and suppose \( \varphi(n) \mid n \); then \((p_1 - 1) \cdots (p_k - 1) \mid p_1 \cdots p_k \); since \( p_1 \cdots p_k \) has at most one 2 there cannot be as many as 2 odd primes in \( n \); thus \( n = 2^{\alpha_1} p^{\alpha_2} \) and 
\[ \varphi(n) = 2^{\alpha_1 - 1} p^{\alpha_2 - 1} (p - 1) \]; if \( p \neq 3 \) then \( p - 1 \) could not divide \( 2p \); hence \( p = 3 \); if \( \alpha_1 = 0 \) then \( p \) cannot be 3 since otherwise again \( p - 1 \) could not divide \( n \); the only cases left are those enumerated in the problem and they all work.

18. \[ \varphi(ab) = ab \prod_{p \mid ab} (1 - \frac{1}{p}) = \]
\[ a \prod_{p \mid a} (1 - \frac{1}{p}) b \prod_{p \mid b} (1 - \frac{1}{p}) \frac{1}{\prod_{p \mid c} (1 - \frac{1}{p})} = \varphi(a) \varphi(b) \frac{c}{\varphi(c)} . \]

19. Let \( c_d \) be the number of numbers among \( 1, 2, \ldots, n \) having a gcd of \( d \) with \( n \); then
\[ n = \sum_{d \mid n} c_d = \sum_{d \mid n} \varphi(\frac{n}{d}) = \sum_{d \mid n} \varphi(d) . \]
20. \[ \sum_{d=1}^{\frac{n}{d}} \varphi(\frac{n}{d}) = \sum_{j=1}^{\frac{n}{d}} \varphi(j) = \sum_{j=1}^{\frac{n}{2}} j = \frac{n(n+1)}{2} \]

Alternatively, this may be done by induction with the induction step:

\[ \sum_{d=1}^{\frac{n+1}{d}} \varphi(\frac{n+1}{d}) = \sum_{d=1}^{\frac{n}{d}} \varphi(\frac{n}{d}) + \varphi(n+1) \]

\[ = \sum_{d=1}^{\frac{n}{d}} \varphi(\frac{n}{d}) + \sum_{d \mid n+1 \atop d \leq n} \varphi(d) + \varphi(n+1) = \frac{n(n+1)}{2} + n + 1 \]

\[ = \frac{(n+1)(n+2)}{2} . \]

21. (See Pólya, Szegö II #69 p. 130)

\[ \sum_{n=1}^{\infty} \frac{\varphi(n) x^n}{1 - x^n} = \sum_{n=1}^{\infty} \sum_{j=1}^{\infty} \varphi(j) x^{jn} = \sum_{k=1}^{\infty} \left( \sum_{d \mid k} \varphi(d) \right) x^{k} \]

\[ = \sum_{k=1}^{\infty} k x^{k} = \frac{x}{(1 - x)^2} . \]

22. If there were only finitely many primes and their product was \( P \) then, for all \( k \),

\[ 1 = \varphi(kP) = kP \prod_{p \mid P} (1 - \frac{1}{p}) , \]

where \( \prod_{p} (1 - \frac{1}{p}) \) is a fixed positive constant.

23. If \( n = p_1 \cdots p_k - \frac{1}{p_i} p_1 \cdots p_k \) then

\[ \varphi(n) = n \prod_{\substack{i=1 \atop i \neq j}}^{k} \left( 1 - \frac{1}{p_i} \right) = p_1 \cdots p_k \prod_{i=1}^{k} \left( 1 - \frac{1}{p_i} \right) . \]
24. i) If \( m \leq x, (m, n) = 1 \) then \( m \) contributes \( 1 \) to the 1\(^{\text{st}}\) term and 0 to all other terms; on the other hand if \( m \leq x \) and \( m \) is divisible by exactly \( j \) of the prime factors of \( n \) then \( m \) contributes \( 1 \) to the 1\(^{\text{st}}\) term, \( j \) to the 2\(^{\text{nd}}\) term, \((\frac{j}{2})\) to the 3\(^{\text{rd}}\) term, \( \ldots \); in all, \( m \) contributes \( 1 - j + \left(\frac{j}{2}\right) - \left(\frac{j}{3}\right) + \cdots + \left(\frac{j}{j}\right) = (1-1)^j = 0 \); hence the result;

ii) Taking \( x=n \) we find

\[
\varphi(n) = \varphi(n, n) = n - \sum_{i=1}^{\infty} \frac{n}{p_i} + \sum_{i,j}^{*} \frac{n}{p_ip_j} - \cdots + (-1)^k \frac{n}{p_1 \cdots p_k} = n \prod_{p|n} \left(1 - \frac{1}{p}\right);
\]

iii) If an integer falls between \( \sqrt{x} \) and \( x \) and is not divisible by any prime smaller than \( \sqrt{x} \) then it is a prime; since \( \varphi(x, p, \ldots p_k) \) enumerates these as well as 1 the result follows.

25. i) By direct calculation;
\[ \sigma(2^{n-1}(2^n - 1)) = \sigma(2^{n-1})\sigma(2^n - 1) = \frac{2^n-1}{2-1} \cdot 2^n = 2 \left\{ 2^{n-1}(2^n - 1) \right\}; \]

iii) let \( n = 2^{k-1} m \), where \( m \) is odd and \( k \geq 2 \);
then \( \sigma(n) = \sigma(2^{k-1})\sigma(m) = (2^k-1)\sigma(m) = 2^k m \);
since \( (2^k-1, 2^k) = 1 \) we have \( \sigma(m) = 2^k t \),
\( m = (2^k-1)t \); hence \( \sigma(m) = 2^k t = (2^k-1)t + t = m + t \); therefore \( t = 1 \) and \( m \) is prime; if \( k \) were not prime then \( 2^k-1 = m \) would not be prime (see the proof of \#6);

iv) since \( 2^4 \) ends in 6 we see that \( 2^{4a} \), \( 2^{4a+1} - 1 \), \( 2^{4a+2} \), \( 2^{4a+3} - 1 \) end, respectively, in 6, 1, 4, 7; thus \( 2^{4a}(2^{4a+1} - 1), 2^{4a+2}(2^{4a+3} - 1) \) end, respectively, in 6, 8; this proves the first assertion; noting that for \( n = 13, 17 \) we have consecutive even perfect numbers (see e.g. the remarks at the end of the chapter) and
observing that each of 13, 17 is of the form $4a+1$ we see that the 5th and 6th consecutive even perfect numbers end in 6; 

\[ \text{v) since } \sigma(n) = \sum_{d \mid n} d = \sum_{d \mid n} \frac{n}{d} = n \sum_{d \mid n} \frac{1}{d} \]

the conclusion is obvious;

\[ \text{vi) if } n = p^a q^b \text{ then } \sigma(n) = \frac{p^{a+1} - 1}{p - 1} \cdot \frac{q^{b+1} - 1}{q - 1} \]

\[ < \frac{p^{a+1} q^{b+1}}{(p-1)(q-1)} = \frac{n \cdot p q}{(p-1)(q-1)} = \frac{n}{(1 - \frac{1}{p})(1 - \frac{1}{q})} \leq \frac{15}{8} n. \]

26. i) \( H(n) = \sum_{d \mid n} \frac{\tau(n)}{d} = \sum_{d \mid n} \frac{\tau(n)}{d} = \frac{n \tau(n)}{\sigma(n)} \); the multiplicativity of \( H \) follows from that of all of \( n, \tau(n), \sigma(n) \);

\[ \text{ii) when } n > 1, \sigma(n) \text{ is smaller than } n\tau(n) \]

since \( n\tau(n) \) may be obtained from \( \sigma(n) \) by replacing each contributor to \( \sigma(n) \) by \( n \);
now \( p \) and \( q \) are distinct primes:

\[
H(p^\alpha) = \frac{p^{\alpha+1}(\alpha+1)(p-1)}{p^{\alpha+1}-1} = \frac{(\alpha+1)(1-\frac{1}{p})}{1-\frac{1}{p^{\alpha+1}}}
\]

\[
\begin{aligned}
&\geq 3 \left(1-\frac{1}{p}\right) \geq 3 \left(1-\frac{1}{3}\right) = 2 \\
&\left(\alpha+1\right)\left(1-\frac{1}{p}\right)
\end{aligned}
\]

for \( p \) odd and \( \alpha \geq 2 \);

\[
2 \left(1-\frac{1}{2}\right) = 2 \text{ for } p=2 \text{ and } \alpha \geq 3
\]

\[
H(pq) = \frac{4pq}{(p+1)(q+1)} \geq \frac{4 \cdot 2 \cdot 3}{(2+1)(3+1)} = 2 \text{ since } \frac{x}{1+x}
\]
is strictly monotone increasing; further, in this last expression we have strict inequality except for \( p=2, q=3 \); these results and multiplicativity of \( H \) guarantee \( H(n) \geq 2 \) except for primes and \( 1, 2, 4, 6 \); checking these we find \( H(n) \leq 2 \) for all of them.

(iii) \( H(m) = \frac{m\tau(m)}{\sigma(m)} = \frac{m \cdot 2m}{2m^2} = \frac{1}{2}m = n \);

(iv) \( H(n) = H(2^{H(n)}-1) H(2^{H(n)}-1) = \frac{H(n)}{H(n)} H(2^{H(n)}-1) \cdot \frac{1}{2} H(n) H(2^{H(n)}-1), \)

from which the conclusion follows;
v) by (ii) every odd composite number \( m \) has \( H(m) > 2 \); since \( 2^{H(m)} - 1 \) is odd and \( H(2^{H(m)} - 1) < 2 \) we conclude \( 2^{H(m)} - 1 \) is prime; thus \( n \) is perfect.

27. i) \( q(ab) = \sum_{d \mid ab} f(d') = \sum_{d \mid a} \sum_{d \mid b} f(d\sigma') \\
= \sum_{d \mid a} f(d') \sum_{d \mid b} f(\sigma') = q(a)q(b); \)

ii) these are all clear except possibly for \( \sigma^0 \); let \( a = 2^s a', b = 2^t b' \) where \( a', b' \) are odd; then \( \sigma^0(ab) = \sigma^0(a'b') = \sigma(a'b') = \sigma(a')\sigma(b') \)
\( = \sigma(a')\sigma(b') = \sigma^0(a)\sigma^0(b). \)
1. i) Since \( \binom{p}{j} = \frac{p!}{(p-j)!j!} \), it is clear that
\( p \mid \binom{p}{j} \) when \( 1 \leq j < p \); consequently
\[
\left( m+n \right)^p - (m^p + n^p) = \sum_{j=1}^{p-1} \binom{p}{j} m^j n^{p-j}
\]
is divisible by \( p \);

(ii) by (i), \( p \) divides \( (m+1)^p - (m^p + 1) \), hence the conclusion follows from
\[
(m+1)^p - (m+1) = ((m+1)^p - (m^p + 1)) + (m^p - m)
\]

(iii) by induction on \( m \); clearly this is true for \( m=1 \) and (ii) is just the induction step.

2. Use the multinomial theorem in exactly the same way the binomial theorem was used in \#1(i); to deduce Fermat's theorem put \( k=m \) and all \( m_j = 1 \).
3. By \( \pi_1(i) \) and the hypothesis we see that
\[ p \mid (m+n)^p \] so \( m = -n + pt \) for some \( t \); thus
\[ m^p + n^p = (-n + pt)^p + n^p = \sum_{j=0}^{p-1} \binom{p}{j} (-n)^j (pt)^{p-j} \]
and this sum is divisible by \( p^2 \) since each summand is divisible by \( p^2 \).

4. i) Clearly there are \( n^p \) strings of length \( p \) altogether and of these exactly \( n \) of them are monocolored;

ii) each distinguishable necklace has exactly \( p \) rotations;

iii) the number of necklaces in (ii) is clearly an integer;

iv) since \( p \) divides the even number \( n^p - n \) and since \( p \) and \( 2 \) are relatively prime, the result follows.
5. i) All primes \( \leq n \) divide \( N \) and hence do not divide \( N+1 \); also 2 cannot divide \( N+1 \) since 
\[ N+1 \text{ is odd;} \]

ii) \[ N^m + 1 = (N+1)(N^{m-1} - N^{m-2} + \cdots - N + 1), \]
when \( m \) is odd;

iii) if \( p = 4k+3 \) is a prime factor of \( N+1 \) then, since \( N+1 \mid N^{2^{k+1}} + 1 \), \( p \) also divides 
\[ N^{2^{k+1}} + 1 = N^{2^{k+1}/2} + 1 = (n!)^{2^{k+1}/2} + 1; \]
but by Fermat's theorem \( p \) divides 
\[ (n!)^p - n! \quad (= n!\{n!\}^{p-1}); \]
since \( p \) does not divide \( N \) (it does divide \( N+1 \)) it cannot divide \( n! \), thus \( p \mid (n!)^{p-1} - 1 \) and 
\[ p \mid (n!)^{p-1} + 1 \] which implies \( p \mid 2 \); but \( p \) is odd so we have a contradiction;

iv) by (iii) all prime factors of \((n!)^2 + 1\) are of the form \( 4k+1 \); further if \( p \mid (n!)^2 + 1 \) then
p does not divide \((m!)^2 + 1\) for \(m > p\) so we can generate infinitely many \(4k+1\) primes.

6. i) \(na \equiv nb \pmod{p}\) implies \(p | n(a-b)\);
since \((n,p) = 1\) the result follows from \(\text{iii}\); 

ii) by (i), \(n, 2n, \ldots, (p-1)n\) are congruent, in some order, to \(1, 2, \ldots, p-1\); multiplying these congruences yields the stated congruence;

iii) using (i) after noting that \(((p-1)! , p) = 1\) we have the desired conclusion.

7. i-iii) Same argument as given in \#6(i)-(iii);

iv) when \(m\) is a prime, \(\varphi(m) = m - 1\).

8. i) Let \(a = 2k+1\); then \(a^2 - 1 = 4k(k+1)\) and since one of \(k, k+1\) is even, the conclusion follows;
ii) by induction; the case $\alpha = 3$ is (i); suppose true for $\alpha$; then

$$a^{2(\alpha+1)} - 1 = (a^{2\alpha+2})^2 - 1 = (a^{2\alpha} - 1)(a^{2\alpha} + 1)$$

now $2^\alpha$ divides the 1st factor on the right and 2 divides the 2nd factor on the right; hence $2^{\alpha+1}$ divides the product and the induction is complete.

9. i) For $p$ an odd prime or $p=2$ and $0 \leq \alpha \leq 2$, $a^{x(p^\alpha)} = a^{x(p^\alpha)} \equiv 1 \pmod{p^\alpha}$, by #7, and for $p=2, \alpha > 2$, $a^{x(2^\alpha)} = a^{2\alpha} - 1 \equiv 1 \pmod{2^\alpha}$, by #8; thus for all $p$ and $\alpha$, $p^\alpha$ divides $a^{x(p^\alpha)} - 1$ which, in turn, divides $a^{x(m)} - 1$, when $p^\alpha \mid m$; this yields the desired result;

ii) for $m$ prime $\varphi(m) = m - 1$;

iii) this is clear because $\kappa(m)$ is a divisor of $\varphi(m)$;
\( w \) since \( m \) is odd, \((2, m) = 1\), so \(2^{x(m)} \equiv 1 \pmod{m}\); but \(2^{x(m)} - 1 | 2^{m-1} - 1\) when \(x(m) | m - 1\).

v) \(561 = 3 \cdot 11 \cdot 17\), \(\varphi(561) = 2 \cdot 10 \cdot 16 = 320\), \(x(561) = \text{lcm}\{2, 10, 16\} = 80\); further \(80 | 560\) but \(320\) does not divide \(560\);

\(341 = 11 \cdot 31\), \(x(341) = \text{lcm}\{10, 30\} = 30\);

\(\varphi(341) = 300\); \(2^{300} \equiv 1 \pmod{341}\), \(2^{40} \equiv 2^{10} \equiv 1 \pmod{341}\) so \(2^{340} \equiv 1 \pmod{341}\); but \(x(341) = 30\) does not divide \(340\).

10. This is clear since \(p\) divides \(2^{p-1} - 1 = (2^{\frac{p-1}{2}} - 1)(2^{\frac{p-1}{2}} + 1)\).

11. i) \(b \geq n - 3\) implies \(n = ab \geq 2(n - 3) = 2n - 6 = n + (n - 6) > n\);

b) if \(2a \geq n - 3\) then \(n = a^2 \geq \frac{n^2 - 6n + 9}{4}\) so \((n - 1)^2 + 8 \leq 0\), contrary to fact;
ii) true for \( n = 6 \) by direct checking; otherwise, if \( a < b \), \( a b (n-3)(n-2) \mid (n-2)! \), while if \( a = b \), \( 2ab \mid (n-2)! \); in any event the conclusion follows.

12. (i) This follows from \# 6 (i);

(ii) if \( x \equiv a \pmod{m} \) then \( ax \equiv x^2 \equiv 1 \pmod{m} \)
so \( x \equiv \pm 1 \pmod{m} \);

(iii) by (i) and (ii) the numbers 2, \( \cdots \), \( p-2 \)
split into disjoint pairs with the product of the numbers in each pair \( \equiv 1 \pmod{p} \);
multiplying these congruences yields the result;

(iv) multiply the congruence in (iii) by the congruence \( p-1 \equiv -1 \pmod{p} \);

(v) if \( n \) is prime then \( n \mid (n-1)! + 1 \) by (iv);
if \( n \mid (n-1)! + 1 \) then, by \# 11, \( n \) may not be a
composite integer > 4; but 4 does not divide 3! + 1 so the conclusion follows.

13. If \( p = 4k+1 \) then
\[-1 \equiv p-1, -2 \equiv p-2, \ldots, -2k \equiv 2k+1 \mod p;\]
multiplying these congruences we find
\[(2k)! \equiv (2k+1) \cdots (p-1) \mod p;\]
multiplying both sides by \((2k)!\) and using Wilson's theorem we obtain
\[(2k)!^2 \equiv (p-1)! \equiv -1 \mod p,\]
from which the result follows.

14. i) The number of different paths, starting from a given vertex, traversing the \( p \)-gons is clearly \((p-1)!\); but each \( p \)-gon corresponds to two paths from the starting vertex, since each vertex is on 2 sides; consequently \( T = \frac{(p-1)!}{2} \);
ii) a regular \( p \)-gon is determined once two consecutive vertices are specified; from any vertex there are \( p-1 \) other possible "next" vertices; but again the two edges on a given vertex causes \( p-1 \) to be twice the number of regular \( p \)-gons;

iii) let \( \alpha = \langle 0, 1, \ldots, p-1 \rangle \) be a polygon in \( T \); if the view of the polygon is the same from each vertex of the pair 0, \( j \) then the same will be true of the pair \( a, a+j \) for all integers \( a \) (modulo \( p \)); taking \( a \) successively equal to \( j, 2j, \ldots, (p-1)j \) we see the view from vertices 0, \( j, 2j, \ldots, (p-1)j \) is always the same; i.e. \( \alpha \) is regular; consequently each element of \( T-R \) gives rise to exactly \( p \) such elements by rotation;

iv) this follows immediately from (iii).
15. i) \((m+n-1)! = (m+n-1) \cdots (m+n-n)(m-1)! \equiv (-1)^n n! (m-1)! \pmod{m+n};\)

\(\hat{\nu}\) noting that \(m \equiv -n \pmod{m+n}\) reduce the left side to the right side by substituting on the left in accordance with (i);

\(\hat{\nu}\) that \((p, k) = 1\) and \(k\) is even is clear; now in \(\hat{\nu}\) put \(n=k, m=p\) and use Wilson's theorem to obtain the result;

\(\hat{\nu}\) with \(p=13, k=22\) we have \((p, k) = 1, k\) even, and the congruence in \(\hat{\nu}\) holds; however \(p+k=35\) is not prime;

\(\nu\) mod \(p\), the congruence of \(\hat{\nu}\) implies \((p+1)! + 1 \equiv 0 \pmod{p}\) so the primality of \(p\) follows from \(\not\equiv 12(\nu) \pmod{p+k}\), since \(p \equiv -k\) the congruence of \(\hat{\nu}\) yields
\[ k! \left( k! (p-1)! + 1 \right) \equiv 0 \pmod{p+k}; \]
but by (i),
\[ k! (p-1)! \equiv (-1)^k (k+p-1)! \pmod{p+k}; \]
thus (recall \( k \) is even)
\[ k! (k! (p-1)! + 1) \equiv k! ((k+p-1)! + 1) \equiv 0 \pmod{p+k} \]
and \( p+k \) is prime, again using \( \#12(v) \);

vi) taking \( p=n, k=2 \) this result follows
from (iii), (v).

16. Write \( n = qs + r, 0 \leq r < s \); then
\[ a^n = (a^s)^q a^r \equiv a^r \equiv 1 \pmod{m}; \]

dence if \( r \neq 0 \) we would have a contradiction
with the definition of \( s \).

17. i) This follows from the proof of \( \#9(v) \);

ii) if \( a \) is as described and \( s \) is the smallest
power of \( a \) which is congruent to \( 1 \) modulo \( m \)
then by \( #16 \) \( s \mid m - 1 \) and \( s \mid \varphi(m) \); by hypothesis
this means \( s = m - 1 \) so \( m - 1 \mid \varphi(m) \); but
\[
\varphi(m) = m \prod_{p \mid m} (1 - \frac{1}{p}) < m - 1
\]
when \( m \) is composite; hence \( m \) is prime under
the conditions stated.

18. (See Guy [1967] for the following solutions.)
For \( p = 1093 \) we have, where all the congruences
are modulo \( p^2 \):
\[
2^{10} = 1024 = p - 69 \text{ so }
\]
\[
2^{14} = 16p - 1104 = 15p - 11 \equiv -1078p - 11 = -11(2 + 98p); \\
\]
thus
\[
11^3 = 1331 = p + 238;
\]

\[
11^4 = 11p + 2618 = 13p + 432 \equiv 432 - 1080p = 2^3 \cdot 3^3(2 - 5p);
\]

\[
3^7 = 2187 = 2p + 1;
\]

using these we find
\[
2^{392} \equiv 11^{28}(1 + 98p)^{28} \equiv \left\{2^3 \cdot 3^3(2 - 5p)\right\}^7 (1 + 2744p)
\]
\[
\equiv 2^{21} \cdot 3^{21}(2^7 - 2^6 \cdot 5 \cdot p)(1 + 558p)
\]
\[
\equiv 2^{27}(2p + 1)^3(2 - 35p)(1 + 558p)
\]
\[
\equiv 2^{27}(1 + 6p)(2 - 12p) \equiv 2^{28}
\]
so
\[
2^{1092} = 2^{3(392 - 28)} \equiv 1;
\]
For \( p = 3511 \) we have, where again all congruences are modulo \( p^2 \):

\[
2^6 \cdot 5 \cdot 11 = 3520 = 3^2 + p \equiv 3^2 - (p-1)p = 3^2(1 - 390p)
\]

\[
3^8 = 81^2 = 6561 = 2 \cdot p - 461 ,
\]

\[
3^{10} = 18p - 4149 = 17p - 638 ;
\]

\[
3^{10} \cdot 11 = 187p - 7018 = 185p + 4 \equiv 4 + 3696p = 2^2(1 + 924p);
\]

\[
3^{12} \cdot 11 (1 - 390p) \equiv 2^8 \cdot 5 \cdot 11 (1 + 924p)
\]

\[
2^8 \cdot 5 \equiv 3^{12} (1 - 1314p), \quad 5^5 = 3125 = p - 386 ,
\]

\[
5^7 = 25p - 9650 = 22p + 883 ;
\]

\[
5^9 = 550p + 22075 = 556p + 1009 ;
\]

\[
5^{11} = 13900p + 25225 = 13907p + 648 \equiv 648 - 3648p = 2^3 \cdot 3 (3^3 - 152p) \equiv 2^3 \cdot 3 (3^3 - 3663p) = 2^3 \cdot 3^3 (3 - 407p)
\]

\[
\equiv 2^3 \cdot 3^3 (3 - 3918p) = 2^3 \cdot 3^4 (1 - 1306p),
\]

\[
2^3 \cdot 3^4 \equiv 5^{11} (1 + 1306p) \text{ and } 2^{12} = 4096 = p + 585
\]

so \( 2^{13} \cdot 3 = 6p + 3510 = 7p - 1 \); now

\[
2^{1755} \cdot 3^{132} \cdot 5^{11} = (2^8 \cdot 5)^{11} 2^3 \cdot 3^4 (2^{13} \cdot 3)^{128}
\]

so \( 2^{1755} \cdot 3^{132} \cdot 5^{11} \equiv \left\{ 3^{12} (1 - 1314p) \right\}^{11} 5^{11} (1 + 1306p)(7p - 1)^{128} \),

\[
2^{1755} \equiv (1 - 1314p)^{11} (1 + 1306p)(1 - 7p)^{128} 1 - 13140p - 8p - 896p = 1 - 14044p = 1 - 4p^2 \equiv 1 \text{ and } 2^{3510} \equiv 1 .
19. i) This was shown for 341 in \#9(iv) and for 561 in \#17(i); for \(n = 161038 = 2 \cdot 73 \cdot 1103\), \(n-1 = 3^2 \cdot 29 \cdot 617, \ 2^9 - 1 = 7 \cdot 73, \ 2^{29} - 1 = 233 \cdot 1103 \cdot 2089\); since 9 and 29 divide \(n-1\) we see that \(2^9 - 1\) and \(2^{29} - 1\) divide \(2^{n-1} - 1\); thus, using \(73 \mid 2^9 - 1\) and \(1103 \mid 2^{29} - 1\), we find \(2^{n-1} - 1\) is divisible by 73 and by 1103; since \(2^n - 2\) is even and divisible by 73 and by 1103 we are done.

(This even pseudoprime was found by Lehmer and the verification is due to Sierpinski.)

ii) we need to show \(F_n \mid 2^{F_n - 2}\); this would follow from \(F_n \mid 2^{F_{n-1} - 1}\); this, in turn, follows from

if \(m < n\) then \(2^{2^n - 1} = (2^{2^m} - 1) \prod_{j=m}^{n-1} (2^{2^j} + 1)\);

iii) since \(n\) is odd and divides the even \(2^n - 2\) there is a \(k\) such that \(2^n - 2 = 2k^n\); hence \(2^{2^n - 2} - 1 = (2^n)^{2k} - 1\) and, since \(2^n - 1 \mid (2^n)^{2k} - 1\),
we conclude $2^{n-1} | 2^{2^{n-2}} - 1$; thus $2^{n-1} | 2^{2^{n-1}} - 2$,
and, since $n$ is odd, $2^n - 1$ is composite; therefore $2^n - 1$ is a pseudoprime;

\[ w) \quad n - 1 = 4 \frac{(2^{p-1} + 1)(2^{p-1} - 1)}{3} \text{ and } 2^{p-1} - 1 \text{ is divisible by each of } p \text{ and } 3 \text{ and hence by } 2p; \text{ thus } 2p | n - 1; \text{ since } n | 2^{2p} - 1, \text{ which, in turn, divides } 2^{n-1} - 1 \text{ we see that } n | 2^{n-1} - 1; \]

\[ v) \text{ immediate from either (iii) or (w).} \]

20. i-a) Because one can add, subtract, and multiply congruences term by term, if respective
coefficients in $F$ and $G$ are congruent modulo $p$, then certainly $F(c_1, \ldots, c_n) \equiv G(c_1, \ldots, c_n) \pmod{p}$;

\[ b) \text{ by Fermat's theorem } c^p \equiv c \pmod{p} \text{ for all } c \text{ so if } F(x) = x^p, G(x) = x \text{ then } F \equiv G \pmod{p}; \]

\[ c) \text{ if } x^n, n \geq p, \text{ appears write } n = qp + r, \quad 0 \leq r < p, \text{ and then replace } x^n = x^{qp+r} \text{ by } x^r; \text{ this is permitted since, by Fermat's theorem, } x^{qp+r} = (x^p)^q x^r \equiv x^r \pmod{p}; \]
d) If \( P(x) = c_0 + c_1 x + \cdots + c_n x^n \) and 
\( P(c) \equiv 0 \pmod{p} \) then 
\[
P(x) - P(c) = (x-c)(d_0 + d_1 x + \cdots + d_{n-1} x^{n-1})
\]
so 
\[
P(x) = P(c) + (x-c)(d_0 + \cdots + d_{n-1} x^{n-1})
\]
thus if \( d_0 + \cdots + d_{n-1} x^{n-1} \) has no more than \( n-1 \) zeros \( \pmod{p} \) then \( P \) has no more than \( n \); since a linear polynomial has exactly 1 zero \( \pmod{p} \), we know a polynomial of degree \( n \) has no more than \( n \) zeros \( \pmod{p} \); thus if \( F \equiv G \pmod{p} \) then, since \( F \equiv G \), of degree \( p-1 \), has \( p \) zeros \( F - G \) must be identically zero; i.e.
\[
F \equiv G \pmod{p};
\]
e) By induction; let
\[
F(x_1, \ldots, x_{n+1}) = \sum_{j=0}^{p-1} F_j(x_1, \ldots, x_n) x_{n+1}^j,
\]
\[
G(x_1, \ldots, x_{n+1}) = \sum_{j=0}^{p-1} G_j(x_1, \ldots, x_n) x_{n+1}^j;
\]
given \( c_1, \ldots, c_n \) let 
\[
F(c_1, \ldots, c_n)(x) = F(c_1, \ldots, c_n, x),
\]
\[
G(c_1, \ldots, c_n)(x) = G(c_1, \ldots, c_n, x),
\]
and note that 
\[
F(c_1, \ldots, c_n)(c) \equiv G(c_1, \ldots, c_n)(c) \pmod{p} \] for all \( c \); thus
For \((c_1, \ldots, c_n) \equiv G(c_1, \ldots, c_n) \mod p\) and, therefore, by 
(\ref{a}), \(F(c_1, \ldots, c_n) \equiv G(c_1, \ldots, c_n) \mod p\); this means 
\(F_j(c_1, \ldots, c_n) \equiv G_j(c_1, \ldots, c_n) \mod p\), \(0 \leq j \leq n\); 
since this is true for all \(n\)-tuples \(c_1, \ldots, c_n\) the 
induction hypothesis guarantees \(F \equiv G \mod p\), 
\(0 \leq j \leq p-1\), and the result follows;

\(a\) clear;

(2) in this case one of the terms in the 
product is congruent to 0 modulo \(p\) so the 
entire product is congruent to 0;

\(b\) \(G(a_1, \ldots, a_n) \equiv 1 \mod p\) and if 
\((x_1, \ldots, x_n) \neq (a_1, \ldots, a_n)\) then \(F^{-1}(x_1, \ldots, x_n) \equiv 1 \mod p\)
so \(G(x_1, \ldots, x_n) \equiv 0 \mod p\); thus \(F \equiv G \mod p\);

\(c\) \(H\) is reduced so this follows from 
(\(b\)) and (\(i-c\));

\(d\) clear;
iii) If the assertion were not true the hypothesis of (ii) would be satisfied and this would lead to the contradiction $n \leq \deg F$
(see (ii-a)) ;

iv) Since a form always has the trivial (all $x_j = 0$) solution this result follows from Chevalley's theorem (iii) ;

v-a) Equivalent reduced forms are identical ;
   b) This is clear from the expression in (a) ;
   c) If $p$ does not divide $s$ then
      \[
      n(p-1) = \deg H^* \leq \deg H = r(p-1)
      \]
      and $n \leq r$ , contrary to fact ;
   d) Immediate from (c) ;

vi) $\deg F \leq n-1$ so $\deg H \leq (n-1)(p-1)$ ; now
\[
\prod_{j=1}^{n} \left( 1 - (x_j - a_j^{(d)})^{p-1} \right) = Q_i(x) + (-1)^n \prod_{j=1}^{n} (x_j - a_j^{(d)})^{p-1},
\]
where $\deg Q_i(x) < n(p-1) - (p-1) = (n-1)(p-1)$,
so that
\[ H^X(x_1, \ldots, x_n) = \sum_{i=1}^n \xi_i Q_i(x) + (-1)^n \sum_{i=1}^n \prod_{j=1}^n (x_j - a_j^{(i)})^{p-1}; \]
since \( \deg H^X \leq \deg H \leq (n-1)(p-1) \) all terms in the 2\textsuperscript{nd} term on the right of degree >\( (n-1)(p-1) \) must have coefficients divisible by \( p \); this 2\textsuperscript{nd} term equals
\[
\sum_{i=1}^n \xi_i \sum_{t_1 \leq \cdots \leq t_n} (-a_i^{(i)})^{P_1-t_1} \cdots \cdots \cdots (-a_n^{(i)})^{P_1-t_n} x_1^{t_1} \cdots x_n^{t_n};
\]
thus all coefficients of terms for which \( t_1 + \cdots + t_n > (n-1)(p-1) \) are divisible by \( p \); this implies
\[ \sum_{i=1}^n (a_i^{(i)})^{P_1-t_1} \cdots (a_n^{(i)})^{P_1-t_n} \equiv 0 \pmod{p} \]
for \( t_1 + \cdots + t_n > (n-1)(p-1) \); taking all \( t_i = p-1 \) except for \( t_j \), which is taken \( \geq 1 \), yields \( t_1 + \cdots + t_n > (n-1)(p-1) \) and
\[ \sum_{i=1}^n (a_i^{(i)})^k \equiv 0 \pmod{p} \]
for \( 0 \leq k \leq p-2 \);
vii) put \( H(x_1, \ldots, x_n) = \prod_{i=1}^{n} (1 - F_i^{p-1}(x_1, \ldots, x_n)) \)
and show \( H^*(x_1, \ldots, x_n) = \prod_{i=1}^{s} \prod_{j=1}^{m} (1 - (x_j - a_j^{(ii)})^{p-1}) \),
where \((a_1^{(ii)}, \ldots, a_n^{(ii)})\), \(1 \leq i \leq s\), are all the solutions of the system; now
\(\deg H^* \leq \deg H = (p-1)(r_1 + \cdots + r_m) \leq (n-1)(p-1)\)
so \(\deg H^* < n(p-1)\) so the highest degree term in \(H^*\) must have a coefficient divisible by \(p\);
this coefficient is \(s\) so \(p \mid s\).
x Divisibility Criteria - Solutions

1. i.e. (i) Let \( n = a_m 10^m + \cdots + a_0 \), \( 0 \leq a_j < 10 \) for all \( j \); then \( n - S_{10}(n) = a_m (10^m - 1) + \cdots + a_1 (10 - 1) \) and, since both 3 and 9 divide \( 10^j - 1 \) for \( j = 1, \ldots, m \), the conclusions follow;

   iii) let \( n = a_m k^m + \cdots + a_0 \), \( 0 \leq a_j < k \) for all \( j \);
then \( n - S_k(n) = a_m (k^m - 1) + \cdots + a_1 (k - 1) \);
since \( d \) divides \( k - 1 \), which in turn divides \( k^j - 1 \),
\( j = 1, \ldots, m \), the conclusion follows as before.

2. i) By \#1 (iii), any common divisor of 6 and \( S_7(p) \) would have to divide \( p \) since
(by \#1 (iii)) 6 divides \( p - S_7(p) \); hence
\( (6, S_7(p)) = 1 \);
ii) the smallest $S_7(p)$ which is composite must be 25 since by (i) we know 5 is the smallest possible prime divisor of $S_7(p)$; now the smallest $n$ with $S_7(n) = 25$ is $(166666)_7$ and this number in base 10 is
\[6(1+7+7^2+7^3)+7^4 = 4801,\]
which is a prime.

iii) the next larger composite value for $S_7(p)$ is $5 \cdot 7 = 35$ and the smallest integer $n$ with $S_7(n) = 35$ is $(566666)_7$, which is
\[6(1+7+7^2+7^3+7^4)+5 \cdot 7^5 > 100000.\]

3. i) This follows from the fact that 11 divides $10^{25} - 1$ and $10^{25+1} + 1$ for all non-negative integral $s$;

ii) as in (i), $k+1$ divides $k^{25} - 1$ and $k^{25+1} + 1$ for all non-negative integral $s$; hence $d$ also divides these quantities.
4. i) clear;

ii) \[ 7 \cdot 11 \cdot 13 = 1001 \] and \[ Q(n) - R(n) = 1001 \cdot Q(n) - n; \]
thus \[ c | Q(n) - R(n) \] if and only if \( c | n \);

iii) we illustrate by means of an example;

it shows 14 824 017 659 to be divisible by 11 but not by either 7 or 13; since -451 is divisible by 11 but not by 7 or 13 the above assertion is correct.

5. i) This is a consequence of #1 (iii);

ii) if \( n = a_0 + a_1 k + \cdots + a_s k^s \) then the highest power of \( k \) in \( n! \) is \[ \left[ \frac{n}{k} \right] + \left[ \frac{n}{k^2} \right] + \cdots + \left[ \frac{n}{k^s} \right] = \]
\[ (a_1 + \cdots + a_s k^{s-1}) + (a_2 + \cdots + a_s k^{s-2}) + \cdots + a_s = a_1 + a_2 (k+1) + a_3 (k^2 + k+1) + \cdots + a_s (k^{s-1} + \cdots + 1) = \]
\[ \frac{a_1}{k-1} k - 1 + a_2 \frac{k^2 - 1}{k-1} + a_3 \frac{k^3 - 1}{k-1} + \cdots + a_s \frac{k^s - 1}{k-1} = \]
\[ \frac{1}{k-1} \left( \frac{a_1 k + a_2 k^2 + \cdots + a_s k^s}{k-1} - (a_1 + \cdots + a_s) \right) = \frac{1}{k-1} \left( n - S_k(n) \right) = T_k(n) \]
iii) by (ii) the highest power of 2 in \( n! \) is \( T_2(n) = n - S_2(n) \) and \( S_2(n) \) is just the quantity \( v \) described.

iv) this is proved by induction; it is clear for \( n = 1 \) so we will assume it to be true for \( N \);

Case 1: \( k \) does not divide \( N + 1 \); then

\[ N + 1 = b_0 + b_1 k + \cdots + b_t k^t, \quad 0 < b_0 \leq k - 1, \text{ and} \]

\[ N = (b_0 - 1) + b_1 k + \cdots + b_t k^t; \text{ hence} \]

\[ S_k(N + 1) = S_k(N) + 1, \quad T_k(N + 1) = T_k(N), \text{ and} \]

\( k \) divides \( N + 1 - b_0 \); therefore,

\[ \left\{ \frac{(N + 1)!}{(N)!} - b_0! \cdots b_t! \right\} = \]

\[ b_0 \left\{ \frac{N!}{(N)!} - (b_0 - 1)! b_1! \cdots b_t! \right\} \pmod{k}, \]

and, since by the induction hypothesis the 2nd bracketed expression is divisible by \( k \),

the induction is complete.
Case 2: \( k \text{ divides } N+1 \); then
\[
N+1 = b_s k^s + \cdots + b_{s+t} k^{s+t}, \quad 0 < b_s, 1 \leq s, \text{ and }
\]
\[
N = (k-1) + \cdots + (k-1) k^{s-1} + (b_s - 1) k^s + \cdots + b_{s+t} k^{s+t};
\]
hence
\[
S_k(N+1) = S_k(N) - s(k-1) + 1,
\]
\[
T_k(N+1) = T_k(N) + s
\]
and \( k \) divides \( \frac{N+1}{k^s} - b_s \); therefore, since by Wilson's theorem, \( k \) also divides \( (k-1)^s \cdot (-1)^s \), we have
\[
\frac{(N+1)!}{(-1)^s T_k(N+1)} - b_s! \cdots b_{s+t}! \equiv \frac{N+1}{(-1)^s T_k(N)} \cdot (-1)^s (k-1)^s b_s! \cdots b_{s+t}! \equiv (-1)^s b_s \left\{ \frac{N!}{(-1)^s T_k(N)} \cdot (k-1)^s (b_s - 1)! \cdots b_{s+t}! \right\} \pmod{k};
\]
since, by the induction hypothesis \( k \) divides the \( 3^{rd} \) expression, the conclusion follows.
Squares - Solutions

1. Put \( N = n(2n+1) \); then
\[
N^2 + (N+1)^2 + \ldots + (N+n)^2 = (N+n+1)^2 + \ldots + (N+2n)^2
\]
as is easily verified; the given equalities are all special cases of this identity.

2. i) Direct verification yields the result;
ii) suitable additions of one or more of \( 1^2, 2^2, 3^2 \) to the following equalities suffice to prove this:

\[
\begin{align*}
129 &= 10^2 + 5^2 + 2^2 \\
130 &= 9^2 + 7^2 \\
132 &= 9^2 + 5^2 + 4^2 + 3^2 + 1^2 \\
133 &= 9^2 + 6^2 + 4^2 \\
138 &= 8^2 + 7^2 + 5^2 \\
141 &= 10^2 + 5^2 + 4^2 \\
149 &= 10^2 + 7^2 \\
152 &= 10^2 + 6^2 + 4^2 \\
155 &= 9^2 + 7^2 + 5^2 \\
166 &= 9^2 + 7^2 + 6^2 \\
171 &= 9^2 + 7^2 + 5^2 + 4^2 \\
173 &= 10^2 + 8^2 + 3^2 \\
174 &= 10^2 + 7^2 + 5^2 \\
182 &= 9^2 + 7^2 + 6^2 + 4^2 \\
189 &= 10^2 + 8^2 + 5^2
\end{align*}
\]
3, i) Solving $x^2 + y^2 = 1$, $y = \lambda (x + 1)$ simultaneously for $x$ yields $(1 + \lambda^2) x^2 + 2\lambda^2 x + (\lambda^2 - 1) = 0$ so $x = \frac{-\lambda^2 + 1}{1 + \lambda^2}$ and, since $x \neq -1$, we find $x = \frac{1 - \lambda^2}{1 + \lambda^2}$, $y = \lambda \frac{1 - \lambda^2}{1 + \lambda^2}$, $\lambda \neq 1$; clearly every rational point on $C'$ corresponds to a line $L_\lambda$ with rational $\lambda$;
ii) from \( x^2 + y^2 = z^2 \) we have \( \left( \frac{x}{z} \right)^2 + \left( \frac{y}{z} \right)^2 = 1 \) so \( \left( \frac{x}{z}, \frac{y}{z} \right) \) is a rational point on \( C' \) and corresponds to a rational \( \lambda \), say \( \lambda = \frac{r}{s} \), \( (r, s) = 1 \); then

\[
\begin{align*}
\frac{x}{z} &= \frac{1 - \lambda^2}{1 + \lambda^2} = \frac{s^2 - r^2}{s^2 + r^2}, \quad \frac{y}{z} &= \frac{2\lambda}{1 + \lambda^2} = \frac{2rs}{s^2 + r^2};
\end{align*}
\]

if \( r \) and \( s \) are of opposite parity then

\[
( s^2 - r^2, s^2 + r^2 ) = (2rs, s^2 + r^2) = 1
\]

and we may put \( u = r, v = s \) giving the indicated expressions for \( x, y, z \); if \( r \) and \( s \) are of the same parity they must be odd and in this case we put \( u = \frac{s - r}{2}, v = \frac{s + r}{2} \) giving the indicated expressions for \( x, y, z \) with \( x \) and \( y \) interchanged.

4. Every odd number leaves a remainder of 1 or 3 when divided by 4 and, therefore, the square of an odd number leaves a remainder of 1 when divided by 4; consequently the sum of two odd numbers squared always leaves a remainder of 2 when divided by 4; but a square never leaves a remainder other than 0 or 1.
5. i) The number of \( am + n \) with \((m, n) \in A\) is 
\((\lceil \sqrt{p} \rceil + 1)^2 > p\) so there must be two of them 
which are congruent modulo \( p \);

ii) without loss of generality assume in (i) 
that \( m > m' \) (\( m \) may not be equal to \( m' \) since 
then \( n = n' \) and \((m, n) = (m', n')\) contrary to 
fact) and note \( a(m - m') \equiv n' - n \pmod{p} \);

put \( y = m - m' \) and \( x = |n' - n| \).

6. i) There are \( ef \) pairs \((s, t)\) with \( 0 \leq s < e \), 
\( 0 \leq t < f \); thus there are \( ef \) numbers at \( +s \) ; 
since \( m < ef \) there must be two of these \( ef \) 
numbers which are congruent modulo \( m \);

proceed as in \# 5 (ii);

ii) take \( e = f = \lceil \sqrt{p} \rceil + 1 \), \( m = p \).
7. We know \( ay \equiv \pm x \pmod{p} \) so \( a^2y^2 \equiv x^2 \pmod{p} \); thus \( (a^2+1)y^2 \equiv x^2+y^2 \equiv 0 \pmod{p} \); since \( 0 < x < \sqrt{p} \), \( 0 < y < \sqrt{p} \) we find \( 0 < x^2+y^2 < 2p \); since \( p \mid x^2+y^2 \) we must have \( p = x^2+y^2 \).

8. \( i) \) See the proof of \#4;

\( ii) \) by \((i)\) and \#7.

9. \( i) \) \( (au+bv)^2+(av-bu)^2 = (a^2+b^2)(u^2+v^2) \equiv 0 \pmod{p} \);

\( ii) \) since \((a, b) = 1\) we know there are \( u, v \) such that \( av-bu = 1 \); choosing such \( u, v \) in \((i)\) yields the desired result;

\( iii) \) suppose an odd prime \( p \) divides \( a^2+b^2 \) where \((a, b) = 1\); then by \((ii)\) \( p \) divides a number of the form \( x^2+1 \) so, by \#7, \( p \) is a sum of two squares, which, by \#8, means \( p \) is of
the form $4k+1$; thus all odd divisors of a sum of relatively prime squares, being products of $4k+1$ primes, are themselves of the form $4k+1$.

10. i) Let $p_n$ be a prime factor of $(n!)^2 + 1$, $n \geq 1$; then, since $p_n > n$, the sequence $p_1, p_2, \ldots$ contains infinitely many different primes and, by #9 (iii), they are all of the form $4k+1$;

ii) since $F_n = 2^{2^n} + 1 = (2^{2^{n-1}})^2 + 1$, the prime factors of $F_n$, all odd, are of the form $4k+1$; since the Fermat numbers are relatively prime in pairs - see III #9 (iv-b) - a sequence of primes whose $n$th term is a factor of $F_n$ is a sequence of pairwise distinct $4k+1$ primes.
11. \(i\) See the proof of \#9(i) ;
\(\ ii\) put \(a = -u\) and \(b = v\) in the identity given in the proof of \#9(i) .

12. \(i\) By \#9(\(\ii\)) no \(4k+3\) prime may divide a sum of 2 relatively prime squares and since only even powers of such primes may divide a sum of 2 non-relatively prime squares the result follows ;

\(\ii\) \(2 = 1^2 + 1^2\), all \(p_i\) are sums of 2 squares, \(q_i^2 = q_i^2 + 0^2\) and the result now follows from \#11(\(i\));

\(\iii\) immediate from \((i)\) and \((\ii)\) .

13. This is merely an algebraic verification.

14. \(i\) The total number of such numbers in \(A \cup B\) is \(p+1\) so the result is immediate ;
\[ n^2 \equiv -1 - m^2 \pmod{p} \] leads to
\[ 0 < sp = n^2 + m^2 + 1 + 0^2 \leq \left( \frac{p-1}{2} \right)^2 + \left( \frac{p-1}{2} \right)^2 + 1 < p^2; \]

\( \frac{1}{2} s < t \leq \frac{1}{2} s \) constitute a complete system of residues modulo \( s \), so we may choose the \( A_j \) as indicated; from
\[ \sum A_j^2 \equiv \sum a_j^2 \equiv 0 \pmod{s} \] we know there is an \( r \) such that \( \sum A_j^2 = sr \) and \( 0 \leq r = \frac{1}{s} \sum A_j^2 \leq s \); if
\[ r = 0 \] or \( r = s \) then all \( A_j = 0 \) or all \( A_j = \frac{s}{2} \); so
\[ sp = \sum a_j^2 \equiv 0 \pmod{s^2} \] which implies
\[ p \equiv 0 \pmod{s} \], contrary to \( 1 < s < p \);

\( rs^2 p = 4 \) follows from \#13; further, each of the right hand parenthetical expressions (see \#13) is clearly congruent to 0 modulo \( s^2 \); hence \( s^2 \) divides both sides and
\[ rp = 4; \]
v) by (iv) each $s > 1$ for which $sp = 4$ leads to an $r$, $0 < r < s$, $rp = 4$; repetition leads to $p = 4$.

vi) Immediate from (v) and #13.

15. If we regard $x, y, z$ and $y, x, z$ as the same triple then by #3(ii) all Pythagorean triples are obtained from the equations

$$x = v^2 - u^2, \quad y = 2vu, \quad z = v^2 + u^2,$$

where $u$ and $v$ are relatively prime integers of opposite parity; further, all such triples are indeed Pythagorean triples as one may easily check; we first show that any single application of one of the matrices $U, A, D$ to a primitive Pythagorean triple leads again to a primitive Pythagorean triple; this follows from
\[
(v^2 - u^2, 2vu, v^2 + u^2) \left( \begin{array}{ccc}
\varepsilon & 2\varepsilon & 2\varepsilon \\
2v & v & 2v \\
2 & 2 & 3
\end{array} \right)
\]

\[
= (v'^2 - u'^2, 2v'u', v'^2 + u'^2),
\]

where \( v' = \frac{1}{2} \left( (1 - \varepsilon + 2\varepsilon)u + (3 + \varepsilon)v \right), \)

\( u' = \frac{1}{2} \left( (1 - \varepsilon)u + (1 + \varepsilon)v \right) \)

in each of the three cases

\( \varepsilon = -v = 1, \quad \varepsilon = v = 1, \quad \varepsilon = v' = -1; \)

also in each of these cases \( u', v' \) are relatively prime integers of opposite parity; we now need to show that every such triple is of the form \((3, 4, 5)A; \) in the three cases above we have

\[
(v', u') = \begin{cases}
(2v - u, v) \\
(2v + u, v) \\
(2u + v, u)
\end{cases}
\]

let \( v', u' \) be given relatively prime integers of opposite parity and suppose \( v' > u' \); there are three cases

(a) \( u' < v' < 2u' \), (b) \( 2u' < v' < 3u' \), (c) \( 3u' < v' \).
in these three cases the triple corresponding to \( u', v' \) comes by applying, respectively, \( u, A, D \) to the triple corresponding to \( u, v \) where

(a) \( v = u', \quad u = 2u' - v' \);

(b) \( v = u', \quad u = v' - 2u' \);

(c) \( v = v' - 2u', \quad u = u' \);

in each case \( u, v \) are relatively prime, of opposite parity, and \( v > u \); further, we note that \( v < v' \) and \( u < u' \); the process must stop when \( v = 2 \), in which case \( u = 1 \) and the triple \((3, 4, 5) = (2^2 - 1^2, 2 \cdot 2 - 1, 2^2 + 1^2)\) is reached.
1. i) Using the binomial theorem we find
\[ b_1^t + \ldots + b_n^t + (c_1 + h)^t + \ldots + (c_n + h)^t = \]
\[ b_1^t + \ldots + b_n^t + \sum_{j=0}^{t} \binom{t}{j} h^{t-j} \frac{p}{i=1} c_i^j, \]
\[ c_1^t + \ldots + c_n^t + (b_1 + h)^t + \ldots + (b_n + h)^t = \]
\[ c_1^t + \ldots + c_n^t + \sum_{j=0}^{t} \binom{t}{j} h^{t-j} \frac{p}{i=1} b_i^j; \]
for \( 0 \leq t \leq m \), these are equal since
\[ b_1, \ldots, b_n = c_1, \ldots, c_n \]
for \( t = m+1 \) the two expressions become
\[ b_1^{m+1} + \ldots + b_n^{m+1} + \sum_{j=0}^{m} \binom{m+1}{j} h^{m+1-j} \frac{p}{i=1} c_i^j + \sum_{i=1}^{n} b_i^1; \]
\[ c_2^{m+1} + \ldots + c_n^{m+1} + \sum_{j=0}^{m} \binom{m+1}{j} h^{m+1-j} \frac{p}{i=1} b_i^j + \sum_{i=1}^{n} b_i^1; \]
again, for the same reason, these are equal;

(ii) \((b_2 + x)^m + \ldots + (b_n + x)^m = \]
\[ \sum_{j=0}^{m} \binom{m}{j} \sum_{i=1}^{n} b_i^{m-j} x^j \]
\((c_2 + x)^m + \ldots + (c_n + x)^m = \]
\[ \sum_{j=0}^{m} \binom{m}{j} \sum_{i=1}^{n} c_i^{m-j} x^j \]
if \( b_2, \ldots, b_n \neq c_2, \ldots, c_n \) it is clear that these two
expressions are equal for all $x$; on the other hand, if they are equal for all $x$ they must have identical coefficients which proves the other direction;

iii) this follows immediately from (i) starting with $1 \equiv 2$.

2. The four instances are clear; suppose that
\[ \sum_{n=1}^{2k+1} (1-a_{n-1})n^t = \sum_{n=1}^{2k+1} a_{n-1}n^t \text{ for } 0 \leq t \leq k; \]
then, by \((i)\),
\[ \sum_{n=1}^{2k+1} (1-a_{n-1})n^t + \sum_{n=1}^{2k+1} a_{n-1}(n+2k+1)^t = \sum_{n=1}^{2k+1} a_{n-1}n^t + \sum_{n=1}^{2k+1} (1-a_{n-1})(n+2k+1)^t \]
for $0 \leq t \leq k+1$; noting that
\[ \sum_{n=1}^{2k+2} a_{n-1}(n+2k+1)^t = \sum_{n=2k+2}^{2k+1} a_{n-1-2k-1}n^t, \]
\[ \sum_{n=1}^{2k+2} (1-a_{n-1})(n+2k+1)^t = \sum_{n=2k+2}^{2k+1} (1-a_{n-1-2k-1})n^t \]
and $a_{n-1-2k-1} = \begin{cases} 0 & \text{if } a_{n-1} = 1 \\ 1 & \text{if } a_{n-1} = 0 \end{cases}$, we see that the above is equivalent to
\[ \sum_{n=1}^{2k+1} (1-a_{n-1})n^t = \sum_{n=1}^{2k+1} a_{n-1}n^t \]
for $0 \leq t \leq k+2$, and the induction step is complete.
3. i) Expanding \((rn+s)^t\) using the binomial theorem and interchanging sums leads to the result by coefficient by coefficient application of \(*2\);

ii) follows as does (i) through using the multinomial theorem.

4. i) Put \(r=2, s=-1\) in \(*3 (i)\) and use \(*1 (ii)\) with \(m=k, n=2^k\);

iii) since the \(d_i\) may be chosen as large as we please this is clear;

iii) by (i), with \(x\) in (i) replaced by \(x+d_i\), we see that \(L_i=R_i\) for each \(i\); thus since for each two products \(U_1 \ldots U_k\) the factors are respectively equal so also are the products;
iv) the 1st part of the assertion is clear; since the \( a_i + b_j \) are all distinct, if we choose \( x \) larger than the largest of the \( a_i + b_j \) then the \( x + a_i + b_j \) will necessarily be distinct; that they are odd follows from the fact that \( x \) and the \( a_i \) are even while the \( b_j \) are odd;

v) this is immediate from (iii) \( \sqcup \) (iv) since all of the products \( u_1 \ldots u_k \) equal \( s \).

5. i) \( ts = s_1 + \ldots + s_t \) and each \( s_j \) is such a sum;

ii) by (i) each \( t_i s \) is a sum of \( k^{th} \) powers; consequently so also is \( t_i s 2^k \) and, therefore, \( ms \);

iii) since all the summands in the \( t_i s \) terms are odd and distinct and since for different \( i \) these are multiplied by distinct powers of 2 none of the terms arising can equal any other;
(ii) This follows from (i) ~ (iii) and the possibility, guaranteed by \(*4(v)\), that the hypothesis of (i) are realizable.

6. Each \((i + 1) \leq (s - 1) + 1 \leq s^2\); hence \(S_r < s^{2k+1}\); the \(S_r\) exhaust the residue classes modulo \(s\) so certainly all integers \(\geq s^{2k+1}\) are writeable in the form \(ms + S_r\); the conclusion now follows from the fact that \(ms\) is the sum of distinct \(k^{th}\) powers all smaller than the smallest \(k^{th}\) power making up \(S_r\).
XIII Continued Fractions—Solutions

1. i) This follows immediately from the definition of $E(x_0, \ldots, x_n)$;

ii) the summands of $E(x_0, \ldots, x_{n+1})$ either contain $x_{n+1}$ or they do not; those containing $x_{n+1}$ are precisely the summands of $E(x_0, \ldots, x_n) x_{n+1}$ while those not containing $x_{n+1}$ are those of $E(x_0, \ldots, x_{n-1})$;

iii) for $n=2$, $E(x_0, x_1, x_2) E(x_1) - E(x_0, x_1) E(x_1, x_2)
\begin{align*}
= (x_0 x_1 x_2 + x_0 + x_2) x_1 - (x_0 x_1 + 1)(x_1 x_2 + 1) = -1 \\
= (-1)^{2-1} \; \text{; assume true for } n, \text{ then}
\end{align*}$

$E(x_0, \ldots, x_{n+1}) E(x_1, \ldots, x_n) - E(x_0, \ldots, x_n) E(x_1, \ldots, x_{n+1})
\begin{align*}
= (x_{n+1} E(x_0, \ldots, x_n) + E(x_0, \ldots, x_{n-1})) E(x_1, \ldots, x_n) \\
- E(x_0, \ldots, x_n) (x_{n+1} E(x_1, \ldots, x_n) + E(x_1, \ldots, x_{n-1})
\end{align*}$

$= - (E(x_0, \ldots, x_n) E(x_1, \ldots, x_{n-1}) - E(x_0, \ldots, x_{n-1}) E(x_1, \ldots, x_n))
\begin{align*}
= -(-1)^{n-1} = (-1)^{(n+1)-1} ;
\end{align*}$
iv) for $n = 3$

\[
E(x_0, x_1, x_2, x_3) E(x_1) - E(x_0, x_1) E(x_1, x_2, x_3) = \\
(x_0 x_1 x_2 x_3 + x_0 x_1 + x_0 x_3 + x_2 x_3 + 1) x_1 - (x_0 x_1 + 1)(x_1 x_3 x_6 + x_1 + x_3) \\
= -x_3 = (-1)^3 x_3 ; \text{ assume true for } n, \text{ then}
\]

\[
E(x_0, \ldots, x_{n+1}) E(x_1, \ldots, x_{n-1}) - E(x_0, \ldots, x_{n-1}) E(x_1, \ldots, x_{n+1}) \\
= (x_{n+1} E(x_0, \ldots, x_n) + E(x_0, \ldots, x_{n-1})) E(x_1, \ldots, x_{n-1}) \\
- E(x_0, \ldots, x_{n-1})(x_{n+1} E(x_1, \ldots, x_n) + E(x_1, \ldots, x_{n-1})) \\
= x_{n+1} (E(x_0, \ldots, x_n) E(x_1, \ldots, x_{n-1}) - E(x_0, \ldots, x_{n-1}) E(x_1, \ldots, x_n)) \\
= x_{n+1} (-1)^n = (-1)^{n+1} x_{n+1} ;
\]

v) for $s = 1, n = 3$ we must have $t = 2$ and, in this case,

\[
E(x_0, x_1, x_2, x_3) E(x_1, x_2) - E(x_0, x_1, x_2) E(x_1, x_2, x_3) = \\
(x_0 x_1 x_2 x_3 + x_0 x_1 + x_0 x_3 + x_2 x_3 + 1)(x_1 x_2 + 1) \\
- (x_0 x_1 x_2 + x_0 + x_2)(x_1 x_2 x_3 + x_1 + x_3) = 1 \\
= (-1)^{2-1+1} E(x_1) E(x_4) ; \text{ assume ok for } s = 1, n = n; \text{ then}
\]

\[
E(x_0, \ldots, x_{n+1}) E(x_1, \ldots, x_t) - E(x_0, \ldots, x_t) E(x_1, \ldots, x_{n+1})
\]
\[ \begin{align*}
&= (x_{n+1}E(x_0, \cdots, x_n) + E(x_0, \cdots, x_{n-1})) E(x_1, \cdots, x_t) \\
&\quad - E(x_0, \cdots, x_t)(x_{n+1}E(x_1, \cdots, x_n) + E(x_1, \cdots, x_{n-1})) \\
&\quad = x_{n+1}(-1)^t E(x_{t+2}, \cdots, x_n) + (-1)^t E(x_{t+2}, \cdots, x_{n-1}) \\
&\quad = (-1)^t E(x_{t+2}, \cdots, x_{n+1}) = (-1)^{t-s+1} E(x_1) E(x_{t+2}, \cdots, x_{n+1});
\end{align*} \]

This proves the result for \( s = 1, n \geq 3 \);

similarly one shows ok for \( s = 2, n = 4 \) and

that if true for \( s = 2, n = n \) then true for

\( s = 2, n \to n+1 \); thus true for \( s = 2, n \geq 4 \); assume now that the formula is correct

for \( s \leq q, n \geq q+2 \); then

\[ 
E(x_0, \cdots, x_n) E(x_{q+1}, \cdots, x_t) E(x_0, \cdots, x_t) E(x_{q+1}, \cdots, x_n) \\
= E(x_0, \cdots, x_n)(E(x_{q+1}, \cdots, x_t) - x_{q+1}E(x_{q+1}, \cdots, x_t)) \\
- E(x_0, \cdots, x_t)(E(x_{q+1}, \cdots, x_n) - x_{q+1}E(x_{q+1}, \cdots, x_n)) \\
= E(x_0, \cdots, x_n)E(x_{q+1}, \cdots, x_t) - E(x_0, \cdots, x_t)E(x_{q+1}, \cdots, x_n) \\
- x_{q+1}(E(x_0, \cdots, x_n)E(x_{q+1}, \cdots, x_t) - E(x_0, \cdots, x_t)E(x_{q+1}, \cdots, x_n)) \\
= (-1)^t(-q+1) E(x_0, \cdots, x_{q-3}) E(x_{t+2}, \cdots, x_n) \\
- x_{q+1}(-1)^{t-q+1} E(x_0, \cdots, x_{q-2}) E(x_{t+2}, \cdots, x_n) \\
= (-1)^tE(x_0, \cdots, x_{q-3}) + x_{q+1}E(x_0, \cdots, x_{q-2}) E(x_{t+2}, \cdots, x_n) \\
= (-1)^{t-(q+1)+1} E(x_0, \cdots, x_{(q+1)-2}) E(x_{t+2}, \cdots, x_n); 
\]
The above argument is sketched as follows: verify the assertion for \( s=1, n=3 \) and \( s=1, n=4 \); then show if the assertion is true for \( s=1, n \leq k \) then it is also true for \( s=1, n=k+1 \); repeat for \( s=2, n=4 \); \( s=2, n=5 \); \( s=2, n \leq k \) implies \( s=2, n=k+1 \); the above shows for \( s=1 \) or \( 2 \) and \( n \geq 3 \) or \( 4 \) that the assertion is correct; suppose now true for \( s \leq q \) and \( n \geq q+2 \); then this leads to the truth for \( s \leq q+1, n \geq q+3 \); this implies the truth for \( s > 0, n \geq s+2 \).

vi) Putting \( s=m, t=m+1, n=2m \) in (v)

yields, after using (ii), and noting \( x_{m+1} = x_m, \ldots, x_{2m} = x_0 \),

\[
E(x_0, \ldots, x_{2m}) E(x_m, x_{m+1}) = E^2(x_0, \ldots, x_{m+1}) + E^2(x_0, \ldots, x_{m-1})
\]

\[
= \left\{ x_{m+1} E(x_0, \ldots, x_m) + E(x_0, \ldots, x_{m-1}) \right\}^2 + E^2(x_0, \ldots, x_{m-2})
\]

\[
= (x_{m+1}^2 + 1) \left\{ E^2(x_0, \ldots, x_m) + E^2(x_0, \ldots, x_{m-1}) \right\} + E^2(x_0, \ldots, x_{m-2})
\]

\[
= E^2(x_0, \ldots, x_m) - 2 x_m E(x_0, \ldots, x_m) E(x_0, \ldots, x_{m-1})
\]

\[
+ x_m^2 E^2(x_0, \ldots, x_{m-1})
\]

\[
= (x_{m+1}^2) \left\{ E^2(x_0, \ldots, x_m) + E^2(x_0, \ldots, x_{m-1}) \right\}
\]

;
since \( E(x_m, x_{m+1}) = x_m x_{m+1} + 1 = x_m^2 + 1 \), cancellation of this factor yields the desired result.

\[ \text{vü) Put } s = m+1, t = m+2, n = 2m+1 \text{ in (v) to obtain} \]

\[ E(x_0, \ldots, x_m, x_{m+1}, x_m, \ldots, x_0) E(x_{m+1}, x_{m+2}) \]
\[ = E(x_0, \ldots, x_m, x_{m+1}, x_{m+2}) E(x_{m+1}, x_m, \ldots, x_0) \]
\[ + E(x_0, \ldots, x_{m-1}) E(x_{m+1}, \ldots, x_0) \]
\[ = x_{m+1} E^2(x_0, \ldots, x_m, x_{m+1}) + E(x_0, \ldots, x_m) E(x_0, \ldots, x_{m+1}) \]
\[ + E(x_0, \ldots, x_{m-1}) E(x_0, \ldots, x_{m-2}) \]
\[ = x_{m+2}(x_{m+1} E(x_0, \ldots, x_m) + E(x_0, \ldots, x_{m-1}) E(x_0, \ldots, x_m, x_{m+1}) \]
\[ + E(x_0, \ldots, x_m) E(x_0, \ldots, x_{m+1}) + E(x_0, \ldots, x_{m-1}) E(x_0, \ldots, x_{m-2}) \]
\[ = (x_{m+1} x_{m+2} + 1) E(x_0, \ldots, x_m) E(x_0, \ldots, x_m, x_{m+1}) \]
\[ + x_{m+2} E(x_0, \ldots, x_{m-1}) (x_{m+1} E(x_0, \ldots, x_m) + E(x_0, \ldots, x_{m-1})) \]
\[ + E(x_0, \ldots, x_{m-1}) E(x_0, \ldots, x_{m-2}) \]
\[ = (x_{m+1} x_{m+2} + 1) E(x_0, \ldots, x_m) (E(x_0, \ldots, x_m, x_{m+1}) \]
\[ + E(x_0, \ldots, x_{m-1}) \]

cancelling the factor \( E(x_{m+1}, x_{m+2}) = x_{m+1} x_{m+2} + 1 \)
yields the desired result.
2. \( E_n = E(1, \ldots, 1) \), where there are \( n \) places;

   (i) clearly \( E_1 = E(1) = 1 \) and, from \( \# 1 ( \ddot{w} ) \),
   \[ E_{n+2} = E_{n+1} + E_n \]

   (ii) from (i) and the definition of \( u_n \);

   (iii) the 1st equality is by induction on \( n \)
   and the 2nd follows from the 1st using the binomial theorem;

\textit{w-a}) \( \# 1 ( \text{i}i \text{i}) \) reads, when one puts all \( x = 1 \),
   \[ E_{n+1} E_{n-1} - E_n^2 = (-1)^{n-1} \]
   so the result follows from (ii) ;

\textit{b}) this follows from \( \# 1 ( \text{i}w) \) almost identically to the argument given in (a) ,
   except that the index needs to be changed by unity ;

\textit{c}) follows from \( \# 1 (\text{v}) \) as in (a) \( \Rightarrow \) (b) above ;

\textit{d}) follows from \( \# 1 (\text{vi}) \) as in (a) \( \Rightarrow \) (b) above .
e) follows from \( \#_1 \) (vii) as in (a) \( \equiv (b) \) above;
\[
f) \quad u_{n-3}u_{n-1} + u_{n-1}u_{n-2} + u_{n-1}u_{n-2} + u_{n-2}^2 \\
= u_{n-1}^2 + u_{n-1}u_{n-2} + u_{n-2}u_n = u_{n-1}u_n + u_{n-2}u_n = u_n^2; \\
g) \quad u_{n-3}^2 + u_{n-2}u_{n-3} + u_{n-2}u_{n-3} + u_{n-3}u_{n-4} \\
= u_{n-3}u_{n-1} + u_{n-2}u_{n-3} + u_{n-2}^2 = u_{n-3}u_{n-1} + u_{n-2}u_{n-1} = u_{n-1}^2.
\]

v) for \( n = 2, 3 \) the assertion is correct; suppose it to be correct for \( n, n+1 \); then
\[
a_{n+2} = a_{n+1} + a_n = (u_{n-1}a + u_n b) + (u_{n-2}a + u_{n-1} b) \\
= u_na + u_{n+1}b
\]
and the assertion is also true for \( n+2 \).

3- i) a) \( [a_0, \ldots, a_n] = a_0 + \frac{1}{E(a_0, \ldots, a_n)} \sum_{i=1}^{n} a_i \)
\[
= a_0 + \frac{\prod_{i=1}^{n} a_i}{E(a_1, \ldots, a_n)} = \frac{E(a_0, \ldots, a_n)}{E(a_1, \ldots, a_n)} = \frac{p_n}{q_n};
\]
\[b) \quad [a_n, \ldots, a_1] = \frac{E(a_1, \ldots, a_n)}{E(a_n, \ldots, a_1)} = \frac{E(a_1, \ldots, a_n)}{E(a_1, \ldots, a_{n-1})} = \frac{q_n}{q_{n-1}}; \]
ii) \( p_k = E(a_o, \ldots, a_k) = a_k E(a_o, \ldots, a_{k-1}) + E(a_o, \ldots, a_{k-2}) \)
\( = a_k p_{k-1} + p_{k-2} ; \)

A similar argument works for \( q_k ; \)

iii) \( \left[ a_o, \ldots, a_{n-1}, a_n + \frac{1}{b} \right] = \left[ a_o, \ldots, a_n, b \right] \)
\( = \frac{E(a_o, \ldots, a_n, b)}{E(a_o, \ldots, a_n, b)} = \frac{b E(a_o, \ldots, a_n) + E(a_o, \ldots, a_{n-1})}{b E(a_o, \ldots, a_n) + E(a_o, \ldots, a_{n-1})} \)
\( = \frac{bp_n + p_{n-1}}{bq_n + q_{n-1}} ; \)

iv-a) this follows from \#1(iii) by taking
\( \alpha_j = a_j \) for all \( j \);

b) this follows from \#1(iv) by taking
\( \alpha_j = a_j \) for all \( j \);

v) from (iv) we have \( \frac{p_{n-2}}{q_{n-2} + q_{n-2}q_n} = \frac{p_n}{q_n} = \frac{p_{n-1}}{q_{n-1}} + \frac{(-1)^{n-1}}{q_{n-1}q_n} \)

and the inequalities not involving \( \alpha \) follow by examining the cases with \( n \) even (odd); for the inequalities involving \( \alpha \) note that if
\( \alpha = [a_1, \ldots, a_n + \frac{1}{b}] \) then
\( \alpha - \frac{p_n}{q_n} = \frac{bp_n + p_{n-1}}{bq_n + q_{n-1}} - \frac{p_n}{q_n} = \frac{p_{n-1}q_n - p_nq_{n-1}}{q_n(bq_n + q_{n-1})} = \frac{(-1)^n}{q_n(bq_n + q_{n-1})} ; \)
vi) this follows from the fact that \( \frac{a + c}{b + d} \) always lies between \( \frac{a}{b} \) and \( \frac{c}{d} \);

vii) in the argument above for (v) we found
\[
| \alpha - \frac{p_n}{q_n} | = \frac{1}{q_n(bq_n + q_{n-1})},
\]
where \( a_{n+1} < b < a_{n+1+1} \); thus
\[
q_{n+1} = a_{n+1}q_n + q_{n-1} < bq_n + q_{n-1} < (a_{n+1+1})q_n + q_{n-1} = q_n + q_{n+1}
\]
and the result follows; (note that \( a_{n+1} < b \) since it is assumed that \( q_{n+1} \) exists);

alternative: the last four terms in the sequence given in (vi) are \( \frac{p_{n+1}}{q_{n+1}}, \alpha, \frac{p_{n+1} + p_n}{q_{n+1} + q_n}, \frac{p_n}{q_n} \);

thus
\[
\frac{1}{q_n(q_{n+1} + q_n)} = \left| \frac{p_n}{q_n} - \frac{p_{n+1} + p_n}{q_{n+1} + q_n} \right| < \left| \frac{p_n}{q_n} - \alpha \right| < \left| \frac{p_n}{q_n} - \frac{p_n}{q_n} \right| = \frac{1}{q_nq_{n+1}};
\]

viii-a) \( | \alpha - \frac{p_n}{q_n} | < \frac{1}{q_nq_{n+1}} = \frac{1}{q_n(a_{n+1}q_n + q_{n-1})} \leq \frac{1}{q_nq_{n-1} + q_n} < | \alpha - \frac{p_{n-1}}{q_{n-1}} | ;
\]

b) \( | \alpha q_n - p_n | < \frac{1}{q_{n+1}} = \frac{1}{a_{n+1}q_n + q_{n-1}} \leq \frac{1}{q_n + q_{n-1}} < | \alpha q_{n-1} - p_{n-1} | ;
\)
ix) the limit exists since bounded monotone sequences always converge; the limits are equal if and only if

\[ \left| \frac{p_{n+1}}{q_{n+1}} - \frac{p_n}{q_n} \right| = \frac{1}{q_n q_{n+1}} \to 0 \text{ as } n \to \infty ; \]

x) immediate from (ix) ;

xi) for \( n = 1 \), \( \frac{p_1}{q_1} = \left[ a_0, a_1 \right] = a_0 + \frac{1}{a_1} = a_0 + \frac{1}{q_0 q_1} \); suppose ok for \( n \), then using (iv-a) with \( n \) replaced by \( n+1 \) and having divided by \( q_n q_{n+1} \) we have

\[ \frac{p_{n+1}}{q_{n+1}} = \frac{p_n}{q_n} + \frac{(-1)^{n}}{q_n q_{n+1}} = a_0 + \frac{1}{q_0 q_1} - \frac{1}{q_1 q_2} + \cdots + \frac{(-1)^{n-1}}{q_{n-1} q_n} + \frac{(-1)^n}{q_n q_{n+1}} ; \]

xii-a) this follows immediately from (iv-a) ;

b) \( q_n = E(a_1, \cdots, a_n) \geq E_n \to \infty \);

since \( \frac{p_n}{q_n} \) has a limit and \( q_n \to \infty \) it must be true that \( |p_n| \to \infty ; \)
c) for \( n = 2, 3 \) we have
\[
q_2 = E(a_1, a_2) = a_1 a_2 + 1 \geq 2 \geq 2^{\frac{2-1}{2}}
\]
\[
q_3 = E(a_1, a_2, a_3) = a_1 a_2 a_3 + a_1 + a_3 \geq 3 \geq 2^{\frac{3-1}{2}}
\]
assume ok up to and including \( n \), then
\[
q_{n+1} = a_{n+1}q_n + q_{n-1} \geq q_n + q_{n-1} \geq 2^{\frac{n}{2} - \frac{1}{2}} + 2^{\frac{n}{2} - 1}
= 2^{\frac{n}{2}}(\frac{1}{\sqrt{2}} + \frac{1}{2}) > 2^{\frac{(n+1)-1}{2}}
\]

d) by (ix) since \( q_nq_{n+1} \rightarrow \infty \) as \( n \rightarrow \infty \);

xiii-a) suppose \( \alpha = [a_0, \cdots, a_{n-1}, a_n] = \frac{\alpha' p_{n-1} + p_n}{\alpha' q_{n-1} + q_n} \),
\[
\beta = [a_0, \cdots, a_{n-1}, a_n] = \frac{\beta' p_{n-1} + p_n}{\beta' q_{n-1} + q_n}
\]
let \( \alpha' = a_n + \alpha'' \), \( \beta' = b_n + \beta'' \), where \( 0 < \alpha'' < 1 \),
\( 0 < \beta'' < 1 \); then \( \beta' - \alpha' = (b_n - a_n) + \beta'' - \alpha'' \)
\[
\geq 1 + \beta'' - \alpha'' > 0 \;
\]
\( \alpha - \beta = \frac{\alpha' p_{n-1} + p_n}{\alpha' q_{n-1} + q_n} - \frac{\beta' p_{n-1} + p_n}{\beta' q_{n-1} + q_n} = \frac{(\beta' - \alpha')(p_{n-2} q_{n-1} - p_{n-1} q_n)}{(\alpha' q_{n-1} + q_n)(\beta' q_{n-1} + q_n)} = \frac{(\beta' - \alpha')(n-1)^{n-1}}{(\alpha' q_{n-1} + q_n)(\beta' q_{n-1} + q_n)} \}
\( < 0 \) if \( n \) is even;
\( > 0 \) if \( n \) is odd;

b) put \( \delta = [d_0, d_1, d_2, \cdots] \), where
\( d_{2k} = c_{2k}, d_{2k-1} = b_{2k-1} \); if \( \alpha < \delta \) then, using
(a), we see that if \( j \) is the first place where \( \delta \) and \( \alpha \) differ then
a_j > a_j \text{ for } j \text{ even}, \quad a_j < a_j \text{ for } j \text{ odd};
but then if \( j = 2k \), \( c_{2k} > a_{2k} \), and if \( j = 2k - 1 \),
\( b_{2k-1} < a_{2k-1} \); since these violate the hypothesis,
we must have \( d \leq \alpha \); the right inequality
is proved in the same way;

c) take all \( c_j = 1 \) and all \( b_j = 2 \); then
\[
\frac{1 + \sqrt{3}}{2} = [1, 2, 1, 2, \ldots] \leq \alpha \leq [2, 1, 2, 1, \ldots] = 1 + \sqrt{3}.
\]

4. Let \( \alpha = \frac{a}{b} \) and suppose
\[
\begin{align*}
a &= a_0 b + r_0 & 0 \leq r_0 < b \\
b &= a_1 r_0 + r_1 & 0 \leq r_1 < r_0 \\
r_0 &= a_2 r_1 + r_2 & 0 \leq r_2 < r_1 \\
r_1 &= a_3 r_2 + r_3 & 0 \leq r_3 < r_2 \\
& \vdots \\
r_{k-3} &= a_{k-1} r_{k-2} + r_{k-1} & 0 \leq r_{k-1} < r_{k-2} \\
r_{k-2} &= a_k r_{k-1} + 0
\end{align*}
\]
then
\[
\frac{a}{b} = a_0 + \frac{r_0}{b} = a_o + \frac{\frac{1}{b}}{\frac{r_0}{r_0}} = a_o + \frac{1}{a_1 + \frac{1}{\frac{r_0}{r_1}}}
\]
\[
= a_o + \frac{1}{a_1 + \frac{1}{a_2 + \ldots + \frac{1}{a_k}}} = [a_{o_1}, \ldots, a_k];
\]

If \(a_k = 1\), then this equals \([a_o, \ldots, a_{k-1} + 1]\);

from \(\alpha = [a_o, a_1, a_2, \ldots, a_n] = [b_o, b_1, \ldots, b_n] = \beta\)

we conclude, unless \(n = 1\) and one of \(a_1, b_1\)
is 1, that \(a_o = [\alpha] = [\beta] = b_o\); continue by induction to get uniqueness.

5. Put \(a_o = [\alpha], a_1 = [\frac{1}{\alpha - a_o}], a_2 = [\frac{1}{\alpha - a_o - a_1}], a_3 = [\frac{1}{\alpha - a_o - a_1 - a_2}], \ldots\); i.e. define \(\alpha, \alpha_1, \alpha_2, \ldots\)

by \(\alpha_1 = \frac{1}{\alpha - a_o}, \alpha_j, a_j \) \(\alpha_j - a_j; \) then \(a_j = [\alpha_j]\);

uniqueness follows from the fact that if \(\alpha = [a_o, a_1, \ldots]\) then \(a_o = [\alpha]\), etc.
6-i) Such a scheme is illustrated by the diagram:

</table>

so the convergents are

\[
\frac{2}{1}, \frac{5}{2}, \frac{7}{3}, \frac{26}{11}, \frac{33}{14}, \frac{59}{25}, \frac{269}{114}, \frac{866}{367},
\]

iii) \( \sigma \psi \)

\[
\frac{2227}{9911} = 0 + \frac{1}{4 + \frac{1}{2 + \frac{1}{4 + \frac{1}{1 + \frac{1}{1 + \frac{1}{6}}}}}}
\]

since
\[
2227 = 0 \cdot 9911 + 2227 \\
9911 = 4 \cdot 2227 + 1003 \\
2227 = 2 \cdot 1003 + 221 \\
1003 = 4 \cdot 221 + 119 \\
221 = 1 \cdot 119 + 102 \\
119 = 1 \cdot 102 + 17 \\
102 = 6 \cdot 17 + 0 \\
\]

<table>
<thead>
<tr>
<th>0</th>

</tbody>
</table>

thus \( \frac{2227}{9911} = \frac{131}{583} \) (cancel 17) ;

\[
\frac{34453}{10349} = 3 + \frac{1}{3 + \frac{1}{26}}
\]
since

\[
34453 = 3 \cdot 10349 + 3406 \\
10349 = 3 \cdot 3406 + 131 \\
3406 = 26 \cdot 131 + 0 \\
\]
\begin{align*}
\frac{34453}{10349} &= \frac{263}{79} \quad \text{(cancel 131)} \\
\pi &= \left[ 3, 7, 15, 1, 292, 1, \ldots \right] \quad \text{so} \\
\begin{array}{cccccccc}
3 & 7 & 15 & 1 & 292 & 1 \\
0 & 1 & 3 & 22 & 333 & 355 & 103993 & 104348 \\
1 & 0 & 1 & 7 & 106 & 113 & 33102 & 33215 \\
\end{array}
\end{align*}

\begin{align*}
|\pi - \frac{355}{113}| &< \left| \frac{355}{113} - \frac{103993}{33102} \right| = \frac{1}{113 \cdot 33102} \\
&= \frac{10^{-7}}{3740526} < 3 \cdot 10^{-7} ;
\end{align*}

vi) one obtains the sequence
\begin{align*}
&3, 25, 47, 69, 91, 113, 135, 157, 179, 201, 223, 245, 267, 289, 311, 333, \frac{355}{113} ; \\
&\frac{223}{71}, \frac{245}{78}, \frac{267}{85}, \frac{289}{92}, \frac{311}{99}, \frac{333}{106} ; \text{ one knows to stop since the next term is } \frac{355}{113} \text{ which is on the other side of } \pi \text{ and is, incidentally, the next convergent after } \frac{333}{106} ;
\end{align*}
\( \frac{1 + \sqrt{5}}{2} = 1 + \frac{\sqrt{5} - 1}{2} = 1 + \frac{1}{\frac{\sqrt{5} - 1}{2}} = 1 + \frac{1}{1 + \frac{\sqrt{5}}{2}} \)

\[ = \left[ 1, 1, 1, 1, \ldots \right] ; \]

\( \text{viii) } \alpha = a + \frac{1}{\alpha + \frac{1}{\alpha + \alpha}} = \frac{a^3 + \alpha a^2 + 2a + \alpha}{a^2 + \alpha a + 1} ; \]

hence
\[ \alpha^2 = a^2 + 2 \text{ and } \alpha = \sqrt{a^2 + 2} ; \]

\( \text{ix) } \sqrt{a^2 - 2} = a - 1 + (\sqrt{a^2 - 2} - (a - 1)) = a - 1 + \frac{1}{\frac{\sqrt{a^2 - 2} + a - 1}{2a - 3}} \]

\[ \frac{\sqrt{a^2 - 2} + a - 1}{2a - 3} = 1 + \frac{\sqrt{a^2 - 2} - (a - 2)}{2a - 3} = 1 + \frac{1}{\frac{\sqrt{a^2 - 2} + a - 2}{2a - 3}} \]

\[ \frac{\sqrt{a^2 - 2} + a - 2}{2} = a - 2 + \frac{\sqrt{a^2 - 2} - (a - 2)}{2} = a - 2 + \frac{1}{\frac{\sqrt{a^2 - 2} + a - 2}{2a - 3}} \]

\[ \frac{\sqrt{a^2 - 2} + a - 2}{2a - 3} = 1 + \frac{\sqrt{a^2 - 2} - (a - 1)}{2a - 3} = 1 + \frac{1}{\sqrt{a^2 - 2} + a - 1} \]

\[ \sqrt{a^2 - 2} + a - 1 = 2(a - 1) + (\sqrt{a^2 - 2} - (a - 1)) ; \]

thus
\[ \sqrt{a^2 - 2} = \left[ a - 1, 1, a - 2, 1, 2(a - 1) \right] ; \]
putting \( a = 5 \) we have \( \sqrt{23} = [4, 1, 3, 1, 8] \);
the expansion for \( \sqrt{a^2 - 2} \) was originally given
by Euler, see Perron I, p 99 [1954].

\((1)\) (see Brousseau [1971])

using the schema of (4) we find

\[
\begin{array}{cccc}
\text{n-3 1's} & \text{n-2 1's} \\
2 & 1 & \cdots & 1 & 3 & 1 & \cdots & 1 \\
0 & 1 & 2 & 3 & \cdots & u_{n-1} & 3u_{n-1} + u_{n-2} & \cdots & \alpha \\
1 & 0 & 1 & 1 & u_{n-3} & 3u_{n-3} + u_{n-4} & \beta
\end{array}
\]

where \( \alpha, \beta \) are the respective \( n^{th} \) terms
of sequences constructed as in \#2 (v) where
the \( a, b \) are as follows:

for \( \alpha, \ a = u_{n-1}, \ b = 3u_{n-1} + u_{n-2} \)

for \( \beta, \ a = u_{n-3}, \ b = 3u_{n-3} + u_{n-4} \),

using the results of \#2 (v) and \#2 (iv-f, q)
we have the desired conclusion.

7. \( i-a \) \( q_k = a_k q_{k-1} + q_{k-2} = q_{k-1}(1 + a_k) + q_{k-2} - q_{k-1} \)
< \( q_{k-1}(1 + a_k + a_k^2 + \cdots) = \frac{q_{k-1}}{1 - a_k} \), when \( q_{k-2} < q_{k-1} \);
and $q_k = a_k q_{k-1} + q_{k-2} \leq (a_k + 1) q_{k-2} < \frac{q_{k-2}}{1-a_k}$, when $q_{k-2} \geq q_{k-1}$;

b) for suitably large $k_0$ the convergence of $\sum_{n=1}^{\infty} a_n$ guarantees that $a_k < 1$ for $k \geq k_0$; now iteratively using (a) we obtain

$$q_k < q_s (1-a_{i_1})^{-1} \cdots (1-a_{i_r})^{-1},$$

where $s \leq k_0$ and $k = i_1 > \cdots > i_r > k_0$;

c) from (b) we see that $q_k$ is bounded since $\prod_{i=k_0}^{\infty} (1-a_i)^{-1}$ converges; consequently $q_k q_{k+1}$ does not tend to $\infty$ and $\#_3(x)$ guarantees the divergence of $[a_0, a_1, \cdots]$;

ii-a) $q_0 \geq \min \{q_0, q_1\} = c$, and, similarly,

$$q_1 \geq c; \text{ if } q_k \geq c \text{ for } k \leq n \text{ then }$$

$$q_{n+1} = a_{n+1} q_n + q_{n-1} \geq c;$$

b) this follows from $q_k = a_k q_{k-1} + q_{k-2}$, the positivity of $a_k$ and $q_{k-1} \geq c$;

c) $q_k + q_{k-1} \geq q_{k-1} + q_{k-2} + c a_k$ for $k \geq 2$; iterating this we find
\[ q_k + q_{k-1} \geq q_0 + q_1 + c \sum_{n=1}^{k} a_n > c \sum_{n=1}^{k} a_n; \]

\( d \): \( q_{k-1} \geq c, q_k \geq c, \) so

\[ q_k q_{k-1} \geq c \frac{q_k + q_{k-1}}{2} > \frac{c^2}{2} \sum_{n=1}^{k} a_n; \]

\( e \): by \#3(\( x \)), \( q_k q_{k+1} \to \infty \) as \( k \to \infty \);

iii) this merely combines (\( i \)) \( \& \) (\( ii \));

iv) the series \( \sum_{n=1}^{\infty} a_n \) always diverges under the given conditions.

8. \( i-a \): There are positive integers \( e, v \) such that \( bx - ay = e, cx - cy = -v \);

solving these equations yields

\[ x = \frac{va + ec}{bc - ad} \geq \frac{a + c}{bc - ad}, y = \frac{vb + ed}{bc - ad} \geq \frac{b + d}{bc - ad}; \]

\( bc - ad \neq 0 \) since \( \frac{a}{b} < \frac{c}{d} \);

b) every fraction lying between \( \frac{a}{b} \) and \( \frac{c}{d} \) has a denominator which is \( \geq b + d \); if one of \( \frac{a}{b}, \frac{c}{d} \) is closer to \( x \) then that fraction is a BA1 to \( x \) (the other fraction may or may not
be a $BA_1$ in this case); 

ii) let $\frac{p_j}{q_j}$ be a convergent to $\alpha$; then either 
\[ \frac{p_{j-1}}{q_{j-1}} < \alpha < \frac{p_j}{q_j} \quad \text{or} \quad \frac{p_j}{q_j} < \alpha < \frac{p_{j-1}}{q_{j-1}} \]
and, since $|p_j q_{j-1} - p_{j-1} q_j| = 1$, we conclude from (i.6) that $\frac{p_j}{q_j}$ is a $BA_1$ to $\alpha$;

iii) by problem #6 (v): 
\[
\frac{3}{1}, \frac{22}{7}, \frac{333}{106}, \frac{355}{113}, \frac{103993}{33102};
\]

iv) by problem #6 (vii) 
\[
\frac{1 + \sqrt{5}}{2} = \left[ 1, 1, 1, \ldots \right] = \lim \frac{E_{n+1}}{E_n} = \lim \frac{U_{n+1}}{U_n};
\]

v) if $\frac{p_{j-1}}{q_{j-1}} < \frac{a}{b} < \frac{p_{j+1}}{q_{j+1}}$ then, using (ii.4) $\Rightarrow #3 (iv-b), \quad$ 
noting that $j$ must be odd, 
\[
B \geq \frac{q_{j-1} + q_{j+1}}{q_{j-1}p_{j+1} - q_{j+1}p_{j-1}} = \frac{a_{j+1}q_{j+2}q_{j-1}}{a_{j+1}} > q_j;
\]
if $\frac{p_{j+1}}{q_{j+1}} < \frac{a}{b} < \frac{p_j}{q_j}$ then, using (ii.4) $\Rightarrow #3 (iv-b), \quad$ 
noting that $j$ must be even, 
\[
B \geq \frac{q_{j+1} + q_{j-1}}{q_{j+1}p_{j-1} - p_{j+1}q_{j-1}} = \frac{a_{j+1}q_{j+2}q_{j-1}}{a_{j+1}} > q_j.
\]
9. i) \( \Phi_1 = \{ \frac{0}{1}, \frac{1}{1} \} \) ; \\
\( \Phi_2 = \{ \frac{0}{1}, \frac{1}{2}, \frac{1}{1} \} \) ; \\
\( \Phi_3 = \{ \frac{0}{1}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{1}{1} \} \) ; \\
\( \Phi_4 = \{ \frac{0}{1}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{1}{1} \} \) ; \\
\( \Phi_5 = \{ \frac{0}{1}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{2}{5}, \frac{1}{2}, \frac{3}{5}, \frac{3}{4}, \frac{3}{5}, \frac{4}{5}, \frac{5}{6}, \frac{1}{1} \} \) ; \\
\( \Phi_6 = \{ \frac{0}{1}, \frac{1}{6}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{2}{5}, \frac{1}{2}, \frac{3}{5}, \frac{3}{4}, \frac{3}{5}, \frac{4}{5}, \frac{5}{6}, \frac{1}{1} \} \) ; \\

ii) clear ;

iii) a) \((a, b) = 1\) so the congruence \(ay \equiv -1 \pmod{b}\) is solvable; choose that residue class for \(y\) so that \(n - b < y \leq n\); 

b) with \(x_0\) and \(y_0\) as specified suppose \((c, d') = 1\) and \(\frac{a}{b} < \frac{c}{d'} < \frac{x_o}{y_0}\); then \(ad + 1 \leq bc\) and \(cy_0 + 1 \leq dx_0 = d' \cdot \frac{ay_0 + 1}{b}\); this implies \(bcy_0 + b \leq ady_0 + d\) and, therefore, \(n < y_0 + b \leq (bc - ad) y_0 + b \leq d\); this means \(\frac{c}{d'}\) is not in \(\Phi_n\) while \(\frac{x_0}{y_0}\) is in \(\Phi_n\);
c) put \( a = 79, b = 101, n = 101 \); then
\[ 79y_0 \equiv -1 \pmod{101} \] and \( 0 < y_0 \leq 101 \) are satisfied by \( y_0 = 23 \); thus \( x_0 = 18 \) and \( \frac{18}{23} \) is the desired fraction in \( \Phi_{101} \); since only the inequality changes to work in \( \Phi_{200} \), and then because
\[ 99 < y_0 \leq 200 \] we see \( y_0 = 23 + 101 = 124 \) in the second case; thus \( x_0 = 97 \) and \( \frac{97}{124} \) is the next fraction after \( \frac{79}{101} \) in \( \Phi_{200} \);

d) let \( m = \max \{ b, d \} \); then since
\[ ad \equiv -1 \pmod{b} \] and \( m - b < d \leq m \) we conclude
\[ \frac{ad + 1}{b} = \frac{ad + 1}{bd} = \frac{bc}{bd} = \frac{c}{d} \]
is the element next after \( \frac{a}{b} \) in \( \Phi_m \);

\( \hat{w} \)-a) if \( b + d \leq n \) then the fraction \( \frac{a + c}{b + d} \)
would be in \( \Phi_n \) and then \( \frac{a}{b}, \frac{c}{d} \) would not
be consecutive in \( \Phi_n \);

b) by \( \hat{w} \), \( \frac{c}{d} = \frac{x_0}{y_0} \) and, therefore,
\[ bc - ad = bx_0 - ay_0 = 1 \]
c) immediate from (6) ;

d) from (6), if $b=d$ then $b=d=1$ and, since \( \frac{a}{2}, \frac{b}{2} \) are consecutive elements only in $\Phi_1, n = 1$; but this violates $n > 1$ ;

v) this follows from $(\dot{w} - b)$ and $\#8 (i - b)$ ;

vi-a) by $(\dot{w} - b)$, $bx - ay = 1$ and $cy - dx = 1$; thus $x = \frac{a+c}{6c - ad}$ and $y = \frac{b+d}{6c - ad}$; since $(x, y) = 1$ this implies $(a+c, b+d) = (6c - ad)$ ;

b) from (a) \( \frac{x}{y} = \frac{a+c}{b+d} \);

vii) clear from (vi) ;

viii) $\Phi_7 = \{ \frac{0}{1}, \frac{1}{7}, \frac{1}{6}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{2}{5}, \frac{3}{7}, \frac{4}{7}, \frac{5}{7}, \frac{1}{2}, \frac{1}{1} \}$ ;

ix-a) all fractions in $\Phi_{n+1} > \Phi_n$ are Farey mediants of fractions in $\Phi_n$ by (vii) ;
consequently the only fraction in \( \Phi_{n+1} \setminus \Phi_n \)
lying between \( \frac{a}{b} \) and \( \frac{c}{d} \) is \( \frac{a+c}{b+d} \); since no fraction of \( \Phi_{n+1} \setminus \Phi_n \) not lying between \( \frac{a}{b} \)
and \( \frac{c}{d} \) can be as close to \( \alpha \) as each of \( \frac{a}{b} \) and
\( \frac{c}{d} \) the conclusion follows;

6) by (v) at least one of \( \frac{a}{b} \) and \( \frac{c}{d} \) is
a BA1 to \( \alpha \); consequently all fractions with
denominators \( \leq n \) are further from \( \alpha \) than
the closer of \( \frac{a}{b}, \frac{c}{d} \); if \( \frac{a+c}{b+d} \) is in \( \Phi_{n+1} \setminus \Phi_n \)
and is closer to \( \alpha \) than the nearer of \( \frac{a}{b}, \frac{c}{d} \),
then clearly it is nearer to \( \alpha \) than all
other elements of \( \Phi_{n+1} \setminus \Phi_n \) and, therefore,
is a BA1 to \( \alpha \);

x) the double underlined terms are the
requisite fractions for \( \pi - 3 : \frac{9}{1}, \frac{1}{8}, \frac{2}{15}, \frac{3}{22}, \frac{4}{29}, \frac{5}{36}, \frac{6}{43} \)
\( \frac{7}{50}, \frac{8}{57}, \frac{9}{64}, \frac{10}{71}, \frac{11}{78}, \frac{12}{85}, \frac{13}{92}, \frac{14}{99}, \frac{15}{106} \}\{ \frac{16}{113}, \frac{1}{1}, \frac{1}{6}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{1}{1} \}

hence the desired fractions for \( \pi \) are:

\( \frac{13}{4}, \frac{5}{7}, \frac{6}{7}, \frac{7}{57}, \frac{64}{71}, \frac{78}{85}, \frac{92}{99}, \frac{106}{113} \).
10. (i) In the contrary case
\[
\frac{1}{bd} = \left| \frac{c}{d} - \frac{a}{b} \right| = \left| \alpha - \frac{a}{b} \right| + \left| \alpha - \frac{c}{d} \right| \geq \frac{1}{2b^2} + \frac{1}{2d^2}
\]
so \((b - d)^2 = b^2 - 2bd + d^2 \leq 0\), which is impossible unless \(b = d\), which does not happen for \(n > 1\);

(ii) let \(\frac{a}{b} \leq \alpha < \frac{c}{d}\), where \(\frac{a}{b}\) and \(\frac{c}{d}\) are neighboring elements of \(\Phi_m\);
if \(\left| \alpha - \frac{a}{b} \right| > \frac{1}{b(m+1)}\) and \(\left| \alpha - \frac{c}{d} \right| > \frac{1}{d(m+1)}\) we also have \(\frac{1}{bd} = \frac{c}{d} - \frac{a}{b} = \left| \alpha - \frac{a}{b} \right| + \left| \alpha - \frac{c}{d} \right| \geq \frac{b + d}{bd(m+1)} \geq \frac{1}{bd}\);

since, by \(\#9\ (iv-a)\), \(b + d > m\); thus, either
\(\left| \alpha - \frac{a}{b} \right| \leq \frac{1}{b(m+1)}\) or \(\left| \alpha - \frac{c}{d} \right| \leq \frac{1}{d(m+1)}\);

since \(b \leq m\) and \(d \leq m\) we may choose \(\frac{a}{b}\) to be \(\frac{a}{b}\) in the 1st case and \(\frac{c}{d}\) in the 2nd case.

11. (i) See \# 4;

(ii) by (i) we may expand each of the numbers \(\frac{p}{t}, 1 \leq t \leq s\), into a scf so that \(a_0 > 1\), \(a_n > 1\);
doing so yields \( \frac{p}{t} = \frac{E(a_0, \ldots, a_n)}{E(a_1, \ldots, a_n)} \);

iii) by \#3 (xii-a), \( p = E(a_0, \ldots, a_n) \) for each of the numbers \( t \) in (ii); if, on the other hand, \( p = E(a_0, \ldots, a_n) \) and \( a_0 > 1, a_n > 1 \), then
\[
\frac{p}{t} = \frac{E(a_0, \ldots, a_n)}{E(a_1, \ldots, a_n)}
\]
is one of the above expansions with \( 1 \leq t \leq s \); the last conclusion follows from \#1 (i);

iv) by (iii) if \( p = E(a_0, \ldots, a_n) \) also
\( p = E(a_n, \ldots, a_0) \); thus these sequences may be paired and, since \( p = E(p) \), the sequence \( p \) is paired with itself; now the evenness of the number of sequences means that one of the other sequences must be the same forwards and backwards; i.e. \( a_j = a_{n-j} \);

v) by \#1 (vii), \( E(a_0, \ldots, a_m, a_{m+1}, a_m, \ldots, a_0) \)
is not a prime when \( a_0 > 1 \);
thus \( p = E(a_0, \ldots, a_m, \ldots, a_0) \), as in (iv), and by *1 (vi), \( p = E^2(a_0, \ldots, a_m) + E^2(a_0, \ldots, a_{m-1}) \);

\[
\begin{align*}
v_i) & \quad s = \left[ \frac{13}{2} \right] = 6, \quad 13 = E(13), \quad \frac{13}{2} = 6 + \frac{1}{2} = \frac{E(6, 2)}{E(2)}, \\
& \quad \frac{13}{3} = 4 + \frac{1}{3} = \frac{E(4, 3)}{E(3)}, \quad \frac{13}{4} = 3 + \frac{1}{4} = \frac{E(3, 4)}{E(4)}, \\
& \quad \frac{13}{5} = 2 + \frac{1}{1 + \frac{1}{2}} = \frac{E(2, 1, 1, 2)}{E(1, 1, 2)}, \quad \frac{13}{6} = 2 + \frac{1}{6} = \frac{E(2, 6)}{E(6)}; \\
\text{the pairs are:} & \quad \frac{13}{2} \leftrightarrow \frac{13}{6}, \quad \frac{13}{3} \leftrightarrow \frac{13}{4}, \\
& \quad 13 \leftrightarrow 13, \quad \frac{13}{5} \leftrightarrow \frac{13}{5}, \quad \text{thus} \\
& \quad 13 = E(2, 1, 1, 2) = E^2(2, 1) + E^2(2) = 3^2 + 2^2.
\end{align*}
\]

12.1-a) \[ \left| \frac{a}{b} - \frac{s}{t} \right| \leq \frac{1}{t([\sqrt{b}] + 1)} < \frac{1}{t \sqrt{b}} \]
and \( 0 < t \leq \left[ \sqrt{b} \right] \leq \sqrt{b} \); thus
\[
0 < (at - bs)^2 + t^2 < \frac{b^2}{b} + b = 2b;
\]
6) from (a),
\[
0 < (at - bs)^2 + t^2 = (a^2 + 1)t^2 - 2abst + b^2 s^2 < 2b
\]
and, since \( b \) divides \( a^2 + 1 \), it also divides the middle expression which implies
\[
(a^2 + 1)t^2 - 2abst + b^2 s^2 = b.
\]
or, what is the same, \( \frac{a^2+1}{b} t^2 - 2 at - bs^2 = 1 \);
if \((at - bs, t) = \delta\) then \(\delta\) divides \(t\) and \(at - bs\)
so \(\delta|bs\); since \((s, t) = 1\) either \(\delta = 1\) or \(\delta|b\);
in the latter case \(\delta\) divides the left side of the
above equation and therefore divides the right
side of the equation and this implies \(\delta = 1\);

\(c)\) this was shown in the proof of \((a)\);

\(ii)\) let \(b\) divide \(a^2 + 1\); then \((a, b) = 1\) and
we may take \(\alpha = \frac{a}{b}\) in \((i)\); the conclusion
\((at - bs)^2 + t^2 = b\) derived in the proof of \((i-a)\)
yields the desired result since by \((b)\)
\[(at - bs, t) = 1;\]

\(iii)\) Wilson's theorem tells us
\[
(p-1)! = (4k)! \equiv -1 \pmod{4k+1};
\]
now \((4k)! = (1 \cdot 2 \cdots (2k))(2k+1) \cdots (4k)\)
\[
= (1 \cdot 2 \cdots (2k))(p-2k) \cdots (p-1)
\equiv (1 \cdot 2 \cdots (2k))^2 (-1)^{2k} = a^2 \pmod{p};\]
i.e. taking \( a = (2k)! \), \( p \) divides \( a^2 + 1 \); the conclusion follows from (ii);

\( \delta \) if \((b, c) = \delta \) then \( \delta | a^2 \) so \( \delta = 1 \); thus there is a \( u \) such that \( cu \equiv 1 \pmod{b} \); thus \((a^2 + c^2)u^2 = (au)^2 + 1 \equiv 0 \pmod{b} \) and we are done;

v) this follows immediately from (ii) \& (iv).

13. i) \[ |\alpha - \frac{a}{b}| \geq |\alpha - \frac{c}{d}| \quad \text{for } d \leq b \implies d | \alpha b - a | \geq b | \alpha d - c | \]
which in turn implies
\[ |\alpha b - a | \geq \frac{b}{d} \mid \alpha d - c | \geq | \alpha d - c | ; \]

ii) \( \frac{1}{2} \) is a BA1 but not a BA2 to \( \frac{1}{2} \);

iii-a) if \( \frac{a}{b} < \frac{p_0}{q_0} = a_0 \) then \( |\frac{a}{b} - \alpha| > |\frac{a_0}{1} - \alpha| \)
so \( \frac{a}{b} \) would not be a BA1 to \( \alpha \);
b) if \( \frac{a}{b} > \frac{p_1}{q_1} \) then \( \alpha < \frac{p_1}{q_1} < \frac{a}{b} \), so
\[
1 \cdot \alpha - a \leq \frac{1}{q_1} = \frac{1}{q_1} = b \cdot \frac{1}{bq_1} \leq b \left| \frac{a}{b} - \frac{p_1}{q_1} \right| < 1 \left| \alpha - \frac{a}{b} \right| = \left| b \alpha - a \right|
\]
so \( \frac{a}{b} \) would not be a BA2 to \( \alpha \);

c) \( b > q_k \) follows from \( \# 8(v) \); clearly
\[
\left| \alpha - \frac{a}{b} \right| \geq \left| \frac{a}{b} - \frac{p_{k+1}}{q_{k+1}} \right| = \left| \frac{aq_{k+1} - b p_{k+1}}{b q_{k+1}} \right| \geq \frac{1}{b q_{k+1}} ;
\]
\[
\left| \alpha - \frac{p_k}{q_k} \right| < \left| \frac{p_{k+1}}{q_{k+1}} - \frac{p_k}{q_k} \right| = \frac{1}{q_k q_{k+1}} ;
\]

d) from (c) we conclude
\[
\left| b \alpha - a \right| \geq \frac{1}{q_{k+1}} > \left| q_k \alpha - p_k \right|
\]
ad this violates our supposition that \( \frac{a}{b} \) is a BA2 to \( \alpha \);

e) we have shown in (a) \( \sim (d) \) that \( \frac{a}{b} \) may not lie between consecutive convergents and also may not lie to the left or right of all convergents; consequently \( \frac{a}{b} \) must be a convergent to \( \alpha \);

\( \# 3(vii) \) we use \( \# 3(vii) \) to derive
\[
\left| q_n \alpha - p_n \right| < \frac{1}{q_{n+1}} = \frac{1}{a_{n+1} q_n + q_{n-1}} \leq \frac{1}{q_n + q_{n-1}} < \left| q_{n-1} \alpha - p_{n-1} \right| ;
\]
6) since \( \alpha \) is between \( \frac{p_{n-1}}{q_{n-1}} \) and \( \frac{p_n}{q_n} \) we know 
\[ |\alpha - \frac{p_{n-1}}{q_{n-1}}| + |\alpha - \frac{p_n}{q_n}| = \frac{1}{q_n q_{n-1}} \]
and multiplying by \( q_n q_{n-1} \) yields the result;

c) no matter how \( \frac{a}{b} \), \( \alpha \), \( \frac{p_{n-1}}{q_{n-1}} \) are arranged on the line
\[ \frac{1}{b q_{n-1}} \leq |\frac{p_{n-1}}{q_{n-1}} - \frac{a}{b}| \leq |\frac{p_{n-1}}{q_{n-1}} - \alpha| + |\alpha - \frac{a}{b}|; \]
now multiply by \( b q_{n-1} \);

d) immediate since the left side is obviously less than or equal to the left side of the inequality in (6);

e) follows by a comparison of the inequalities in (c) and (d);

f) immediate from (e);

v) this is merely a restatement of (iii-e) and (w-f).

14. Assume the contrary for \( \frac{p_k}{q_k}, \frac{p_{k+1}}{q_{k+1}} \) and deduce \( (q_k - q_{k+1})^2 \leq 0. \)
15. i) If $\frac{a}{b} = \alpha$ then $\alpha' = 0$; otherwise

$$|\alpha - \frac{p_s}{q_s}| < \frac{1}{q_s^2} < \frac{1}{q_s q_{s-1}} = \left|\frac{p_{s-1}}{q_{s-1}} - \frac{p_s}{q_s}\right|$$

so either

(n even) \quad \begin{array}{c}
\frac{a}{b} = \frac{p_s}{q_s} \\
\alpha \quad \frac{p_{s-1}}{q_{s-1}}
\end{array}

or (n odd) \quad \begin{array}{c}
\frac{p_{s-1}}{q_{s-1}} \quad \alpha \quad \frac{a}{b} = \frac{p_s}{q_s}
\end{array}

in either event $\alpha' = \frac{\alpha - \frac{p_s}{q_s}}{\frac{p_{s-1}}{q_{s-1}} - \alpha} \cdot \frac{q_s}{q_{s-1}} > 0$;

now, by $*3$ (iii),

$$[a_0, \ldots, a_s + \alpha'] = \frac{1}{\alpha'} \frac{p_s + p_{s-1}}{q_s + q_{s-1}} = \alpha$$

ii) \quad \frac{1}{\alpha'} + \frac{q_{s-1}}{q_s} = \frac{p_{s-1} - \alpha q_{s-1}}{\alpha q_s - p_s} + \frac{q_{s-1}}{q_s}

$$= \frac{(-1)^s}{q_s^2(\alpha - \frac{a}{b})} = \frac{1}{b^2|\alpha - \frac{a}{b}|} > 2$$

thus $\frac{1}{\alpha'} > 2 - \frac{q_{s-1}}{q_s} > 1$ so $\alpha' < 1$; also we know $\alpha' > 0$ by (i); since $\alpha' < 1$ and $\alpha = [a_0, \ldots, a_s + \alpha']$, by (i), the final conclusion follows from (ii);

iii) this is an immediate consequence of (ii);
iv) this follows from the fact that the interval \( \left( \frac{a}{b} - \frac{1}{2b^2}, \frac{a}{b} + \frac{1}{2b^2} \right) \) contains uncountably many real numbers for each of which \( \frac{a}{b} \) is a convergent;

v) (see Gessel [1972]) suppose \( n \) is a Fibonacci number; then for some positive integer \( k \), \( n = \frac{1}{\sqrt{5}} \left\{ \left( \frac{1+\sqrt{5}}{2} \right)^k - \left( \frac{1-\sqrt{5}}{2} \right)^k \right\} \); thus \( 5n^2 = \left( \frac{1+\sqrt{5}}{2} \right)^{2k} + 2(-1)^{k+1} + \left( \frac{1-\sqrt{5}}{2} \right)^{2k} \)

and, therefore,
\[
\left\{ \left( \frac{1+\sqrt{5}}{2} \right)^k + \left( \frac{1-\sqrt{5}}{2} \right)^k \right\}^2 = \begin{cases} 
5n^2 + 4 \text{ when } k \text{ is even;} \\
5n^2 - 4 \text{ when } k \text{ is odd;}
\end{cases}
\]

the converse is true for \( n = 1 \) so let \( n \geq 2 \) and suppose \( 5n^2 \pm 4 = m^2 \); then \( k = \frac{m+n}{2} \) is an integer since \( m \) and \( n \) have the same parity; further \( m^2 = 4n^2 + n^2 \pm 4 \geq 4n^2 \) so \( m \geq 2n \); substituting \( 2k - n \) for \( m \) in our equation yields \( 5n^2 \pm 4 = 4k^2 - 4kn + n^2 \) or
\[
\frac{\pm 1}{n^2} = \left( \frac{k}{n} \right)^2 - \left( \frac{k}{n} \right) - 1 = \left( \frac{k}{n} - \tau \right) \left( \frac{k}{n} - \tau' \right),
\]
where \( \tau = \frac{1 + \sqrt{5}}{2} \), \( \tau' = \frac{1 - \sqrt{5}}{2} \); hence

\[
\left| \frac{\ell}{n} - \tau \right| = \frac{1}{n^2} \left| \frac{1}{n} - \tau' \right| < \frac{1}{2n^2} \quad \text{since}
\]

\[
\frac{\ell}{n} - \tau' = \frac{1}{2} \left( \frac{m}{n} + 1 \right) - \tau' \geq \frac{3}{2} - \frac{1 - \sqrt{5}}{2} = 1 + \frac{\sqrt{5}}{2} > 2 ;
\]

therefore, by (iii) , \( \frac{\ell}{n} \) is a convergent to \( \tau \), say

\[
\frac{\ell}{n} = \frac{u_{s+1}}{u_s} , \quad \text{and} \quad n = u_s \quad \text{as desired} .
\]

16. (a) \[
\frac{1}{q_s q_{s-1}} = \left| \frac{p_s}{q_s} - \frac{p_{s-1}}{q_{s-1}} \right| = \left| \alpha - \frac{p_s}{q_s} \right| + \left| \alpha - \frac{p_{s-1}}{q_{s-1}} \right|
\]

\[\geq \frac{1}{\sqrt{5}} \left( \frac{1}{q_s^2} + \frac{1}{q_{s-1}^2} \right) ; \]

b) each of \( \frac{q_s}{q_{s-1}} \) and \( \frac{q_{s-1}}{q_s} \) when substituted for \( \alpha \) in \( x^2 - \sqrt{5} x + 1 \) makes this quantity \( \leq 0 \); thus these rational numbers must lie strictly between the irrational zeros \( \frac{\sqrt{5} \pm 1}{2} \) of this quadratic ;

c) each of \( \frac{q_{s+1}}{q_s} \) and \( \frac{q_{s-1}}{q_s} \) is between \( \frac{\sqrt{5} + 1}{2} \) and \( \frac{\sqrt{5} + 1}{2} \) so their distance apart is less than \( \frac{\sqrt{5} + 1}{2} - \frac{\sqrt{5} - 1}{2} = 1 ; \)

d) by (c), in the contrary case, \( a_{s+1} \) would be a positive integer smaller than 1;
e) this follows immediately from (d) since there exist infinitely many disjoint triplets of consecutive convergents to $\alpha$;

\[ \frac{a}{b} = \frac{u_{n-1}}{u_n} \text{ for some } n; \text{ hence } \]
\[ \left| \frac{1 + \sqrt{5}}{2} u_{n-1} - u_n \right| < \frac{\beta}{\sqrt{5} u_{n-1}} \text{ and, therefore, using } \]
\[ \left| \frac{\lambda^{2n+1}}{2} \left( \left( \frac{1 + \sqrt{5}}{2} \right)^{n+1} \right) + \left( \frac{1 + \sqrt{5}}{2} \right)^n \right| < \frac{\beta}{\left( \frac{1 + \sqrt{5}}{2} \right)^n} \]
\[ \text{or} \]
\[ \left| \left( \frac{\sqrt{5} - 1}{2} \right)^{2n+1} + \left( \frac{\sqrt{5} - 1}{2} \right)^{2n+1} \pm \sqrt{5} \right| < \beta \sqrt{5}; \]
since $\beta < 1$ and the left side tends to $\sqrt{5}$ this happens only for finitely many values of $n$;

(alternate argument)

suppose $\lambda < \frac{1}{\sqrt{5}}$ and $\left| \frac{1 + \sqrt{5}}{2} - \frac{a}{b} \right| < \frac{\lambda}{b^2}$;
then $\frac{1 + \sqrt{5}}{2} - \frac{\lambda}{b^2} < \frac{a}{b} < \frac{1 + \sqrt{5}}{2} + \frac{\lambda}{b^2}$ so
\[ \frac{\sqrt{5} b}{2} - \frac{\lambda}{b} < a - \frac{b}{2} < \frac{\sqrt{5} b}{2} + \frac{\lambda}{b} ; \]
this implies $\frac{\lambda^2}{b^2} - \sqrt{5} \lambda < a^2 - ab - b^2 < \frac{\lambda^2}{b^2} + \sqrt{5} \lambda$ and, therefore, for large enough $b$,
\[-1 < a^2 - ab - b^2 < 1; \text{ hence } a^2 - ab - b^2 = 0\]
and \(\frac{a}{b} = \frac{1 \pm \sqrt{5}}{2}\) which is impossible;

\[\text{iii-a)} \text{ as in (i-b), each of } \frac{q_{s+1}}{q_s} \text{ and } \frac{q_{s-1}}{q_s} \text{ lies in} \]
\(\left(\frac{\sqrt{m^2+4} - m}{2}, \frac{\sqrt{m^2+4} + m}{2}\right); \text{ hence } a_{s+1} = \frac{q_{s+1}}{q_s} - \frac{q_{s-1}}{q_s} < m;\]
\[b) \text{ if no such } s_0 \text{ exists then there are} \]
ininitely many disjoint triples \(s-1, s, s+1\)
for which \(a_{s+1} \geq m; \) consequently by (a)
there are infinitely many convergents
satisfying \(|\alpha - \frac{p_n}{q_n}| < \frac{1}{q_n \sqrt{m^2+4}};\)
\[c) \text{ put } m=2 \text{ in (b)};\]

\[\text{iv-a)} \text{ from } \sigma 3(\text{vi}) \text{ we find} \]
\[q_n| q_n \alpha - p_n | < \frac{q_n}{q_{n+1}} < 1 \text{ and, therefore, } v(\alpha) \leq 1;\]
\[b) \text{ by Hurwitz'} \text{ theorem} \]
\[q_n| q_n \alpha - p_n | < \frac{1}{\sqrt{5}} \text{ infinitely often}; \]
consequently \(v(\alpha) \leq \frac{1}{\sqrt{5}};\)
\[c, d) \text{ same argument as in (b)};\]
\[e) \text{ by (d)};\]
\[ n-a) \quad q_n \left| q_n \alpha - p_n \right| = q_n^2 \left| \alpha - \frac{p_n}{q_n} \right| \\
= q_n^2 \left| \frac{\alpha_n p_n + p_{n-1}}{\alpha_n q_n + q_{n-1}} - \frac{p_n}{q_n} \right| = \frac{1}{\alpha_n + \frac{q_{n-1}}{q_n}} \; ; \\
\]

b) \( \# 3 (1-6) \) gives the equality and the 1st inequality is a consequence of \( \# 3 (xiii-c) \); finally, the result \( q_n \left| q_n \alpha - p_n \right| > \frac{1}{2\sqrt{3}} = \frac{1}{\sqrt{12}} \) shows \( \nu(\alpha) \geq \frac{1}{\sqrt{12}} \; ; \)

c) either infinitely many \( a_j \) are \( \geq 3 \) or all but a finite number are \( \leq 2 \); in the 1st case \( \nu(\alpha) \leq \frac{1}{\sqrt{13}} \) by (w-e) and in the 2nd case \( \nu(\alpha) \geq \frac{1}{\sqrt{12}} \) by (b).

17. i) Let \( \alpha = [a_o, \ldots, a_s, a_{s+1}, \ldots, a_{s+t}] \), \( \alpha_s = [a_{s+1}, \ldots, a_{s+t}] \); then
\[
\alpha = [a_o, \ldots, a_s, \alpha_s] = [a_o, \ldots, a_{s+t}, \alpha_s] \\
= \frac{\alpha_s p_s + p_{s-1}}{\alpha_s q_s + q_{s-1}} = \frac{\alpha_s p_{s+t} + p_{s+t-1}}{\alpha_s q_{s+t} + q_{s+t-1}} \; ;
\]
from the 4th equality we see \( \alpha_s \) satisfies a quadratic equation and, since its scf expansion is infinite, must be irrational;
hence $\alpha_s$ and, therefore also, $\alpha$ is a quadratic irrational;

\(\text{i}\) \ a) \quad \text{by (i):}

\[ b,c) \quad \alpha = [\alpha_0, \ldots, \alpha_n, \alpha_n] = \frac{\alpha_n p_n + p_{n-1}}{\alpha_n q_n + q_{n-1}} \quad \text{so}
\]

\[ o = A\alpha^2 + B\alpha + C = A(\alpha_n p_n + p_{n-1})^2 + 
B(\alpha_n p_n + p_{n-1})(\alpha_n q_n + q_{n-1}) + C(\alpha_n q_n + q_{n-1})^2
\]

\[ = q_n^2 f\left(\frac{p_n}{q_n}\right) \alpha_n^2 + 2 A p_{n-1} p_n + B p_n q_{n-1} + 
B p_{n-1} q_n + 2 C q_{n-1} q_n \alpha_n + q_{n-1}^2 f\left(\frac{p_{n-1}}{q_{n-1}}\right)
\]

direct calculation shows

\[ B_n^2 - 4A_n C_n = B^2 - 4AC ;
\]

the expressions for $A_n, C_n$ are clear;

since $f(\alpha) = 0$ and $\alpha$ is between $\frac{p_{n-1}}{q_{n-1}}$ and $\frac{p_n}{q_n}$, then the values of $f$ at these points are of opposite sign since the other zero of the quadratic does not lie between $\frac{p_{n-1}}{q_{n-1}}$ and $\frac{p_n}{q_n}$; this shows $A_n C_n < 0$ ;
\(a)\) since \(B_n^2 - 4A_nC_n = B_n^2 + 4A_nC_n\) is a constant it is clear that only finitely many such triples exist;

e) by the Dirichlet box principle such \(k\) and \(n\) exist for which \(A_{n+k} = A_k, B_{n+k} = B_k,\)
\(C_{n+k} = C_k\); thus \(\alpha_k = \alpha_{n+k}\), and this means \(\alpha\) is periodic;

\(\text{iii-a)}\) if \(\alpha\) is purely periodic then \(a_o > 0\)
so \(\alpha > 1\); further, \(\alpha = [a_o, \ldots, a_s + \frac{1}{x}] = \frac{\alpha p_s + p_{s-1}}{\alpha q_s + q_{s-1}}\) so \(q_s \alpha^2 + (q_{s-1} - p_s)\alpha - p_{s-1} = 0\);
the roots are \(\frac{p + \sqrt{\Delta}}{\alpha}\), where \(P = p_s - q_{s-1}\),
\(\Delta = (q_{s-1} - p_s)^2 + 4q_s p_{s-1}\), \(Q = 2q_s\); clearly \(\sqrt{\Delta} > P\) so \(\alpha = \frac{P + \sqrt{\Delta}}{Q}\) and \(\alpha' = \frac{P - \sqrt{\Delta}}{Q} < 0\) is the other zero; thus
\(\alpha \alpha' = -\frac{p_{s-1}}{q_s} = -\frac{p_{s-1}}{q_{s-1}} \frac{q_{s-1}}{q_s} > -\alpha \frac{q_{s-1}}{q_s} > -\alpha\)
for \(s\) odd; hence \(\alpha' > -1\) (\(s\) even is similar).
(alternative) at 0 and -1 the quadratic equals
- \( p_{s-1} < 0 \) and \( q_s - q_{s-1} + p_s - p_{s-1} > 0 \); hence \( \alpha' \),
the other zero, lies between 0 and -1;

b) from \(-1 < \alpha' < 0 < 1 < \alpha\) we deduce
\( 0 > - \frac{1}{1 + a_0} > \frac{1}{\alpha' - a_0} = \alpha'_0 > - \frac{1}{a_0} \geq -1 \);

c) from (b) by iteration;

d) \( \alpha_{s-1} - \alpha_{s+t-1} = \)
\[ [a_s, a_{s+1}, \ldots, a_{s+t}] - [a_{s+t}^t, a_{s+1}, \ldots, a_{s+t}] = \]
\( a_s + \frac{1}{[a_{s+1}, \ldots, a_{s+t}]} - a_{s+t} = \frac{1}{[a_{s+1}, \ldots, a_{s+t}]} = a_s - a_{s+t} \);

the second equation follows from the first
since the conjugate operator is additive;

e) since each of \( \alpha'_{s-1} \) and \( \alpha'_{s+t-1} \) are
strictly between -1 and 0 their difference
must lie strictly between -1 and 1; but
then \( a_s = a_{s+t} \) contrary to our
assumption;

f) this is a direct consequence of (a) \( \Rightarrow \) (e);
iv-a) since \( \frac{1+\sqrt{13}}{3} > 1 \) and \(-1 < \frac{1-\sqrt{13}}{3} < 0\) the scf expansion, by (iii-f), is purely periodic; since \( \frac{1-\sqrt{13}}{3} < 1 \) and \( \frac{2+\sqrt{13}}{4} < 1 \) neither of these is reduced, hence neither has a purely periodic scf expansion;

\[ b) \quad \frac{1+\sqrt{13}}{3} = 1 + \frac{\sqrt{13} - 2}{3} = 1 + \frac{1}{1 + \frac{1}{\sqrt{13} + 3}} \]

\[ = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{\sqrt{13} + 3}}} \]

\[ = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{6 + \frac{1}{1 + \frac{1}{\sqrt{13} + 3}}}}} \]

\[ = \left[ 1, 1, 1, 6, 1 \right] ; \]

noting that \(-\left( \frac{1-\sqrt{13}}{3} \right)^{-1} = \frac{\sqrt{13} + 1}{4}\) the above calculation tells us

\[-\left( \frac{1-\sqrt{13}}{3} \right)^{-1} = \left[ 1, 6, 1, 1, 1 \right] ;\]
c) let \( \alpha_{-1} = \alpha = [a_0, \ldots, a_s] \); then for \( 0 \leq j \leq s \) we have \( \alpha_{j-1} = a_j + \frac{1}{\alpha_j} \); in the particular case \( j = s \) we have
\[
\alpha_{s-1} = a_s + \frac{1}{\alpha_s} = a_s + \frac{1}{\alpha} ;
\]
consequently \(- (\alpha_j')^{-1} = a_j + \frac{1}{(\alpha_j')}; \) for \( 0 \leq j \leq s \), and putting \( \beta_j = -(\alpha_j')^{-1} \) yields
\[
\beta_j = a_j + \frac{1}{\beta_{j-1}} \quad \text{for } 0 \leq j \leq s ;
\]
hence
\[
-(\alpha')^{-1} = \beta_s = a_s + \frac{1}{\beta_{s-1}} = a_s + \frac{1}{a_{s-1} + \frac{1}{\beta_{s-2}}}
\]
\[
= a_s + \frac{1}{a_{s-1} + \frac{1}{a_{s-2} + \frac{1}{a_{s-3} + \cdots + \frac{1}{a_0 + \frac{1}{\beta_{-1}}}}}}
\]
\[
= [a_s, \ldots, a_0] ;
\]

v) put \( a_0 = [\alpha] \) and let \( \beta = \alpha_a^{-1} \); since \( 0 < \alpha - a_0 < 1 \), \( \beta > 1 \); further,
\[
-1 < \beta' = \alpha_a^{-1} a_0 = -\frac{1}{\alpha_a} - a_0 < 0
\]
so \( \beta \) is reduced and, therefore, has a purely periodic scf expansion, say \( \beta = [a_1, \ldots, a_k, \delta] ; \)
now \(- (\beta')^{-1} = [b, a_k, \ldots, a_1]\) while

\[- (\beta')^{-1} = a_o + (-\alpha') = a_o + \alpha; \text{ thus}\]

\[b = [- (\beta')^{-1}] = [a_o + \alpha] = a_o + [\alpha] = 2a_o;\]

therefore \(\alpha = a_o + \frac{1}{b} = [a_o, a_1, \ldots, a_k, 2a_o];\)

vi-a) clearly \(\frac{1}{\sqrt{b} - a_o} > 1;\) further, since

\[-1 < \frac{1}{\sqrt{b} - a_o} < 0,\] the number \(\frac{1}{\sqrt{b} - a_o}\) is reduced;

b) \(\sqrt{b} + a_o = - (\frac{1}{\sqrt{b} - a_o})^{-1}\) so its period is

the reverse of that of \(\frac{1}{\sqrt{b} - a_o}\); also

\(\sqrt{b} + a_o > 1\) and \(-1 < -\sqrt{b} + a_o < 0\) so \(\sqrt{b} + a_o\)

is reduced;

c) by (v), \(\sqrt{b} = [a_o, a_1, \ldots, a_k, 2a_o]\) so

\(\frac{1}{\sqrt{b} - a_o} = [a_1, \ldots, a_k, 2a_o]\) and, therefore,

by (iii-f) \(\frac{1}{\sqrt{b} - a_o}\) is reduced; hence by (6)

\(\sqrt{b} + a_o = [2a_o, a_k, \ldots, a_1]\)

but \(\sqrt{b} + a_o = [2a_o, a_1, \ldots, a_k, 2a_o] = [2a_o, a_1, \ldots, a_k];\)

consequently, by uniqueness,

\[a_1 = a_k, \ a_2 = a_{k-1}, \ldots\]

and the desired result follows;
vii-a) \( x_0^2 - Dy_0^2 = 1 \) implies \( \left( \frac{x_0}{y_0} \right)^2 = D + \frac{1}{y_0^2} \); thus \( \frac{x_0}{y_0} = \sqrt{D + \frac{1}{y_0^2}} > \sqrt{D} \) and \( \frac{x_0}{y_0} + \sqrt{D} > 2\sqrt{D} > 2 \); this means, since \((x_0 - \sqrt{D} y_0)(x_0 + \sqrt{D} y_0) = 1\), that
\[
\left| \frac{x_0}{y_0} - \sqrt{D} \right| = \frac{1}{y_0^2} \left| \frac{x_0}{y_0} + \sqrt{D} \right| < \frac{1}{2y_0^2}
\]
and, by \#15 (iii), \( \frac{x_0}{y_0} \) is a convergent to \( \sqrt{D} \);

6-A) \( \sqrt{D} = [a_0, \ldots, a_s + \alpha_s] = \frac{\alpha_s p_s + p_{s-1}}{\alpha_s q_s + q_{s-1}} \) so
\[
\alpha_s (p_s^2 - D q_s^2) + 2 \alpha_s (p_{s-1} p_s - D q_{s-1} q_s) + (p_{s-1}^2 - D q_{s-1}^2) = 0 \quad \text{and}
\]
\[
A_s = p_s^2 - D q_s^2 = x_0^2 - D y_0^2 = 1 \;
\]
\[
C_s = p_{s-1}^2 - D q_{s-1}^2 \;
\]
\[
B_s^2 = 4(p_{s-1}^2 - D q_{s-1}^2 + D(p_{s-1} q_s - p_s q_{s-1})^2) = 4(C_s + D); \]

B) \( \alpha_s = \frac{-B_s \pm \sqrt{B_s^2 - 4C_s}}{2} = \frac{-B_s \pm \sqrt{4D}}{2} = -\frac{1}{2} B_s \pm \sqrt{D}; \)

note now that since \( p_s^2 - D q_s^2 = 1 > 0 \) we must have \( C_s = p_{s-1}^2 - D q_{s-1}^2 < 0 \) so \(-\frac{1}{2} B_s - \sqrt{D} = \pm \sqrt{C_s + D} - \sqrt{D} < 0 \); since \( \alpha_s > 0 \) we then have \( \alpha_s = -\frac{1}{2} B_s + \sqrt{D} \);
C) from \((B)\), \(\sqrt{B} = \frac{1}{2} B_s + \alpha_s\)
\(= [\frac{1}{2}B_s + a_{s+1}, a_{s+2}, \ldots, a_{s+k+1}]\) and since
\(\sqrt{B} = [a_o, a_1, \ldots, a_{k-1}, 2a_o]\) we must have
\(a_o = \frac{1}{2} B_s + a_{s+1}, 2a_o = a_{s+k+1}\);

since \(a_{s+1} = a_{s+k+1}\) we conclude \(-\frac{1}{2} B_s = a_o\)
and \(\alpha_s = a_o + \sqrt{B}\).

D) \(\alpha_s = [a_{s+1}, a_{s+2}, \ldots] = [2a_o, a_1, a_2, \ldots]\)
and the uniqueness guarantees \(a_j = a_{s+j+1}\) for \(j \geq 1\);

E) let \(s = qk + r, 0 \leq r < k\); then
\(a_j = a_{s+j+1} = a_{qk+r+j+1} = a_{r+j+1}\)
so the minimum period \(k\) of the scf expansion
of \(\sqrt{B}\) is \(\leq r+1\); but \(r+1 \leq k\) so \(r+1 = k\) and
\(r = k-1\); thus \(s = q(k+1) = (q+1)(k-1) \equiv -1\) (mod \(k\));

c) this follows immediately from (a) and (b-E);

d') \(\sqrt{B} = \frac{(a_o + \sqrt{B})p_{k-1} + p_{k-2}}{(a_o + \sqrt{B})q_{k-1} + q_{k-2}}\) and multiplication
by the denominator on the right and equating rational and irrational parts yields the
expressions for \(p_{k-1}\) and \(Dq_{k-1}\).
now multiplying the 1st by \( p_{tk-1} \), the 2nd by \( q_{tk-1} \) and subtracting yields the result;

e) this is immediate from (d) ;

\[
\sqrt{22} = \left[ 4, 1, 2, 4, 2, 1, 8 \right]
\]

\[
\begin{array}{cccccc}
0 & 1 & 4 & 5 & 14 & 61 \\
1 & 0 & 1 & 1 & 3 & 13 \\
\end{array}
\]

\[
\sqrt{13} = \left[ 3, 1, 1, 1, 1, 6 \right]
\]

\[
\begin{array}{cccccc}
0 & 1 & 3 & 4 & 7 & 11 \\
1 & 0 & 1 & 1 & 2 & 3 \\
\end{array}
\]

\[
\sqrt{33} = \left[ 5, 1, 2, 1, 10 \right]
\]

\[
\begin{array}{cccc}
0 & 1 & 5 & 6 \\
1 & 0 & 1 & 3 \\
\end{array}
\]

\( q \) see, for example, the number theory book by Niven and Zuckerman [1966].
18. i) \( b = q_n = E(a_1, \ldots, a_n) \geq E_n \);

\( \overline{\text{ii}) by induction} \)
\( \tau < E_2, \quad \tau^2 = 1 + \tau < E_1 + E_2 = E_3; \)
\( \tau^n = \tau^{n-2} + \tau^{n-1} < E_{n-1} + E_n = E_{n+1} \) for \( n \geq 2 \);

\( \overline{\text{iii}) } (\frac{1 + \sqrt{5}}{2})^n < E_n \leq b \) so the result follows by taking logarithms;

\( \overline{\text{iv}) } 5 \log \frac{1 + \sqrt{5}}{2} > 5 (0.20898) > 1 \) and \( \log b < t \); thus \( n < \frac{\log b}{\log \frac{1 + \sqrt{5}}{2}} < 5t \);

\( \overline{\text{v}) immediate from the above when one observes that } n \text{ is just the number of divisions required} \);

\( \overline{\text{vi}) see the references following I #6} \).
19. i) The square of the distance between the centers of \( C(\frac{a}{b}) \) and \( C(\frac{c}{d}) \) is:

\[
\left(\frac{c}{d} - \frac{a}{b}\right)^2 + \left(\frac{1}{2d^2} - \frac{1}{2b^2}\right)^2 = \frac{1}{4b^4} + \frac{2(bc-ad)^2-1}{2b^2d^2} + \frac{1}{4d^4}
\]

\[
\geq \frac{1}{4b^4} + \frac{1}{2b^2d^2} + \frac{1}{4d^4} = \left(\frac{1}{2b^2} + \frac{1}{2d^2}\right)^2;
\]

thus the circles are disjoint unless \( bc-ad=\pm 1 \); precisely when \( bc-ad=\pm 1 \) the circles are tangent and, by \# 9 (iii·d) the fractions \( \frac{a}{b}, \frac{c}{d} \) are neighboring in \( \Phi_m \), where \( m = \max \{ b, d \} \);

ii) the point of tangency has:

\( \text{x-coordinate} = \frac{a}{b} + \frac{1}{2b^2 + \frac{1}{2d^2}} \left( \frac{c}{d} - \frac{a}{b} \right) = \frac{ab+cd}{b^2+d^2}; \)

\( \text{y-coordinate} = \frac{1}{2b^2} + \frac{1}{2b^2 + \frac{1}{2d^2}} \left( \frac{1}{2d^2} - \frac{1}{2b^2} \right) = \frac{1}{b^2+d^2}; \)

iii) this is a consequence of each of \#10 (i) and \#14;
iv-a) all points of tangency are between $\frac{a}{b}$ and $\frac{c}{d}$ and, consequently, so is the entire curvilinear triangle; thus $\alpha$ must lie between $\frac{a}{b}$ and $\frac{c}{d}$;

b) by (i) and #9 (vi-b);

c) each of $b$ and $d'$ is $< b + d = f$;

d') $\frac{a'}{b'} = 1 - \frac{c}{d'}$, $\frac{c'}{f'} = 1 - \frac{c}{f}$, $\frac{c'}{d'} = 1 - \frac{a}{b}$, and $b' = d'$, $f' = f$, $d' = b$;

e) by proof of (d).

20. i)

\[ \begin{array}{cc}
\text{B} \leq \text{A} < \text{C} & \quad & \text{A} \leq \text{B} < \text{C}
\end{array} \]

ii) A and C are points on $C(\frac{c}{d})$ and since $f > b > d'$, the point C is farther to the right than is A;
\[ \begin{align*}
&\text{iii. } a, b \quad B - A = \frac{ab + ef}{b^2 + f^2} - \frac{ab + cd}{b^2 + d^2} \\
&= \frac{b^2c^2 - bc}{(b^2 + (b + d)^2)(b^2 + d^2)} = \frac{t^2 - t - 1}{d^2(t^2 + (t+1)^2)(t^2+1)},
\end{align*} \]

where \( t = \frac{b}{d} \); now \( x^2 - x - 1 \) has zeros at \( \frac{1 + \sqrt{5}}{2} \) and \( t^2 - t - 1 \) is negative precisely between these zeros; thus if \( \frac{b}{d} < \frac{1 + \sqrt{5}}{2} \) then \( B - A < 0 \) and if \( \frac{b}{d} > \frac{1 + \sqrt{5}}{2} \) then \( B - A > 0 \).

\[ \begin{align*}
&\text{iv. a) } |\alpha - \frac{c}{d}| < |A - \frac{c}{d}| = |\frac{ab + cd}{b^2 + d^2} - \frac{c}{d}| \\
&= \frac{b}{d} \frac{ad - bc}{b^2 + d^2} = \frac{1}{d^2} \frac{b}{d} (b/d)^2 + 1 < \frac{1}{\sqrt{5} d^2} \\
&\text{since (putting } t = \frac{b}{d}) \frac{t}{t^2 + 1} < \frac{1}{\sqrt{5}} \text{ when } t > \frac{1 + \sqrt{5}}{2};
\end{align*} \]

\[ \begin{align*}
&\text{b) } |\alpha - \frac{e}{f}| = |B - \frac{e}{f}| = |\frac{ab + ef}{b^2 + f^2} - \frac{e}{f}| \\
&= \frac{6}{f} \cdot \frac{1}{f^2} \frac{\left(\frac{b}{d}\right)^2 + \left(\frac{b + d}{d}\right)^2}{\left(\frac{b}{d}\right)^2 + \left(\frac{d}{d+1}\right)^2} < \frac{1}{f^2 \sqrt{5}} \\
&\text{since (putting } t = \frac{b}{d}) \frac{t(t+1)}{t^2 + (t+1)^2} < \frac{1}{\sqrt{5}} \text{ when } t < \frac{1 + \sqrt{5}}{2};
\end{align*} \]

\[ \begin{align*}
&\text{v) immediate from (iv) and } x^2(t+1) < \frac{1}{\sqrt{5}} \text{.}
\end{align*} \]
21. i) The function $f(x, y) = y - ax$ is continuous, vanishes only on $L$ and is negative at $(1, 0)$ and positive at $(0, 1)$.

ii) $P_{n-2}P_n = (q_n - q_{n-2}, p_n - p_{n-2})$
    $= (a_nq_{n-1}, a_np_{n-1}) = a_n(q_{n-1}, p_{n-1}) = a_nOP_{n-1}$;

iii) the area of $OP_{n-1}P_n$ is the absolute value of
    \[
    \frac{1}{2} \left| \begin{array}{cc} q_n & p_n & 1 \\ q_{n-1} & p_{n-1} & 1 \\ 0 & 0 & 1 \end{array} \right| = \pm \frac{1}{2};
    \]
    if $(s, t)$ were a lattice point in or on the triangle other than the vertices then the area of the triangle $OP_{n-1}P_n$ would be $\geq$ the sum of the absolute values of the following quantities
    \[
    \frac{1}{2} \left| \begin{array}{cc} q_{n-1} & p_{n-1} & 1 \\ s & t & 1 \\ 0 & 0 & 1 \end{array} \right|, \quad \frac{1}{2} \left| \begin{array}{cc} q_n & p_n & 1 \\ s & t & 1 \\ 0 & 0 & 1 \end{array} \right|;
    \]
    since $(q_{n-1}, p_{n-1}) = (q_n, p_n) = 1$ neither of these is $0$ and each is numerically $\geq \frac{1}{2}$;

iv) immediate from (iii).
22. i-a) \[ \frac{a_{n+1} x^{2s}}{a_n x^{2(s-1)}} = \frac{x^2}{2(2n+2s+3)} < 1 \text{ for large } n; \]

b) \[ \text{LHS} = \sum_{s=0}^{\infty} \left\{ \frac{(n+s)!}{s!(2n+2s)!} - \frac{(4n+2)(n+1+s)!}{s!(2n+2+2s)!} \right\} x^{2s} \]

= \[ 2 \sum_{s=1}^{\infty} \frac{(n+s)!}{(s-1)!(2n+2s+1)!} x^{2s} = 2x^2 \sum_{s=0}^{\infty} \frac{(n+s+1)!}{s!(2n+2s+3)!} x^{2s} \]

= \[ 4x^2 \sum_{s=0}^{\infty} \frac{(n+2+s)!}{s!(2n+2s+4)!} x^{2s} = \text{RHS}; \]

c) \[ f_0(x) = \sum_{s=0}^{\infty} \frac{x^{2s}}{(2s)!} = \frac{e^x + e^{-x}}{2}, \]

\[ f_1(x) = \frac{1}{2} \sum_{s=0}^{\infty} \frac{x^{2s}}{(2s+1)!} = \frac{1}{2x} \sum_{s=0}^{\infty} \frac{x^{2s+1}}{(2s+1)!} = \frac{1}{2x} \frac{e^x - e^{-x}}{2}, \]

and, therefore, \[ \frac{f_0(x)}{f_1(x)} = 2x \frac{e^{2x} + 1}{e^{2x} - 1}; \]

d) \[ \frac{e^{2x} + 1}{e^{2x} - 1} = \frac{1}{2x} \frac{f_0(x)}{f_1(x)} = \frac{1}{2x} \left( 2 + 4x^2 \frac{f_2(x)}{f_1(x)} \right) \]

= \[ \frac{1}{x} + \frac{3}{x} + 2x \frac{f_3(x)}{f_2(x)} = \left[ \frac{1}{x}, \frac{3}{x} + 2x \frac{f_3(x)}{f_2(x)} \right] \]

= \[ \cdots = \left[ \frac{1}{x}, \frac{3}{x}, \cdots, \frac{2n-1}{x} + 2x \frac{f_{n+1}(x)}{f_n(x)} \right] \]

= \[ \left[ \frac{1}{x}, \frac{3}{x}, \cdots, \frac{2n-1}{x} + \frac{2x}{4n+2+4x^2} \frac{f_{n+2}(x)}{f_{n+1}(x)} \right] \]

\[ \rightarrow \left[ \frac{1}{x}, \frac{3}{x}, \cdots, \frac{2n+1}{x}, \cdots \right], \]

which converges by Seidel's theorem #7(iii);
\[ ii-a \] \[ p_{3n+1} = p_{3n} + p_{3n-1} = 2p_{3n-1} + p_{3n-2} \]
\[ = (4n+1)p_{3n-2} + 2p_{3n-3} = (4n+2)p_{3n-2} + 2p_{3n-3} - p_{3n-2} \]
\[ = (4n+2)p_{3n-2} + p_{3n-3} + p_{3n-4} + p_{3n-5} - p_{3n-2} \]
\[ = (4n+2)p_{3n-2} + p_{3n-5} \]

and the same equations are true with all \( p \)'s replaced by \( q \)'s.

\[ 6) \quad \frac{c+1}{c-1} = [2, 6, 10, 14, 18, \ldots] \] and the first few convergents for \( \frac{P_n}{Q_n} \) are \( \frac{2}{1}, \frac{13}{6}, \frac{132}{61} \);

for \( n = 0, 1, 2 \) the quantity \( \frac{\frac{1}{2}(p_{3n+1} + q_{3n+1})}{\frac{1}{2}(p_{3n+1} - q_{3n+1})} \)

is \( \frac{1}{2} . 4, \frac{1}{2} . 26, \frac{1}{2} . 264 \); thus the result is true

for \( n = 0, 1, 2 \); now assuming the result true up to and including \( n - 1 \) we have

\[ \frac{p_{3n+1} + q_{3n+1}}{p_{3n+1} - q_{3n+1}} = \frac{(4n+2)(p_{3n-2} + q_{3n-2}) + (p_{3n-5} + q_{3n-5})}{(4n+2)(p_{3n-2} - q_{3n-2}) + (p_{3n-5} - q_{3n-5})} \]

\[ = \frac{(4n+2)P_{n-1} + P_{n-2}}{(4n+2)Q_{n-1} + Q_{n-2}} = \frac{P_n}{Q_n} \];

we now use the fact that

\[ (\frac{1}{2}(p_{3n+1} + q_{3n+1}), \frac{1}{2}(p_{3n+1} - q_{3n+1})) = 1 \]

for all \( n \);
c) \( t_n = \frac{p_{3n+1}}{q_{3n+1}} \), so \( t_n \to \alpha \) and
\[
\frac{t_{n+1}}{t_n} - \frac{e+1}{e-1} = \frac{2(e-t_n)}{(t_n-1)(e-1)} \to 0;
\]
since
\[
\frac{t_{n+1}}{t_n} = \frac{1 + \frac{1}{t_n}}{1 - \frac{1}{t_n}} \not\to 1 \text{ we see } \{t_n\} \text{ is bounded; hence from } \frac{2(e-t_n)}{(t_n-1)(e-1)} \to 0 \text{ we conclude that } t_n \to e, \text{ and uniqueness of limits guarantees }
\alpha = e;
\]

\[\text{iii-a) put } \alpha = \frac{\sqrt{2}}{2} \ln (i-d);\]

b) \( \sqrt{2} \left[ \sqrt{2}, 3\sqrt{2}, 5\sqrt{2}, 7\sqrt{2}, \ldots \right] \)
\[
= \sqrt{2} \left( \sqrt{2} + \frac{1}{3\sqrt{2} + \frac{1}{5\sqrt{2} + \frac{1}{7\sqrt{2} + \ldots} } } \right)
\]
\[
= 2 + \frac{1}{3 + \frac{1}{10 + \frac{\sqrt{2}}{7\sqrt{2} + \frac{1}{9\sqrt{2} + \ldots} } } }
\]
\[
= 2 + \frac{1}{3 + \frac{1}{10 + \frac{1}{7 + \frac{1}{18 + \ldots} } } }
\]
\[
= \left[ 2, 3, 10, 7, 18, \ldots \right],
\]
and this is non-periodic since the partial quotients are unbounded;

c) if $e^{\sqrt{2}}$ were rational then $\sqrt{2} \frac{e^{\sqrt{2}} + 1}{e^{\sqrt{2}} - 1}$ would be a quadratic irrational and would have a periodic scf expansion in violation of (6).

23. i. i) True for $n = 0$; suppose true for $n - 1$; then:

\[
\begin{pmatrix} a_0 & 1 \\ 1 & 0 \end{pmatrix} \cdots \begin{pmatrix} a_n & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} p_{n-1} & p_{n-2} \\ q_{n-1} & q_{n-2} \end{pmatrix} \begin{pmatrix} a_n & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} a_n p_{n-1} + p_{n-2} & p_{n-1} \\ a_n q_{n-1} + q_{n-2} & q_{n-1} \end{pmatrix} = \begin{pmatrix} p_n & p_{n-1} \\ q_n & q_{n-1} \end{pmatrix} ;
\]

\[\frac{p_{n-1}}{q_{n-1}} \to \alpha, \quad \frac{p_n}{q_n} \to \alpha;\]

\[\text{iii) A}_1 \cdots \text{A}_n = \begin{pmatrix} \hat{k}_1 & \hat{k}_2 \\ \hat{k}_3 & \hat{k}_4 \end{pmatrix} \text{ and } \frac{\hat{k}_1}{\hat{k}_3} \to \alpha;\]

now \[\text{A}_1 \cdots \text{A}_n = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \hat{k}_1 & \hat{k}_2 \\ \hat{k}_3 & \hat{k}_4 \end{pmatrix} = \begin{pmatrix} a \hat{k}_1 + b \hat{k}_3 & a \hat{k}_2 + b \hat{k}_4 \\ c \hat{k}_1 + d \hat{k}_3 & c \hat{k}_2 + d \hat{k}_4 \end{pmatrix} \text{ and }\]

\[\frac{a \hat{k}_1 + b \hat{k}_3}{c \hat{k}_1 + d \hat{k}_3} = \frac{a \hat{k}_1 + b}{c \hat{k}_1 + d} \to a \alpha + \frac{b}{\alpha + d};\]
\( iv \) \ if \ \ A_1, \ldots, A_n = \begin{pmatrix} e & f \\ q & h \end{pmatrix} \) \ then \\
\( (k_1 A_1) \cdots (k_n A_n) = \begin{pmatrix} k_1 \cdots k_n e & k_1 \cdots k_n f \\ k_1 \cdots k_n q & k_1 \cdots k_n h \end{pmatrix} \) \\
and \( \frac{k_1 \cdots k_n e}{k_1 \cdots k_n q} = \frac{e}{q} \)

\( v \) subsequences of convergent sequences converge and to the same limit \\

\( vi \) \( |K_1(P_n) - K_2(P_n)| = \frac{|P_n - r_n|}{q_n s_n} = \frac{|P_n s_n - q_n r_n|}{|q_n s_n|} = \frac{1}{|q_n s_n|} \frac{\det P_n}{\det A_n} \)

\( vii. a) \) \ from \ (vi), \ \frac{1}{|q_n s_n|} = |K_1(P_n) - K_2(P_n)| \rightarrow 0;

\( b) \) \ if \ either \ a \ or \ c \ is \ zero \ then \\
\( K_1(P_n B) = K_1(P_n) \rightarrow \alpha \); \ if \ neither \ a \ nor \ c \ is \ 0 \ then \ K_1(P_n B) = \frac{a p_n + c r_n}{a q_n + c s_n} \) \ is \ a \ Farey \ mediant \ of \\
\( \frac{p_n}{q_n}, \frac{r_n}{s_n} \) \ and, \ therefore, \ lies \ between \ them; \\
since \ these \ two \ fractions \ tend \ to \ \alpha \ \ so \\
also \ does \ K_1(P_n B) ;

\( c) \) \ same \ argument \ as \ in \ (b) ;

\( d) \) \ immediate \ from \ (b) \ and \ (c) ;
viii) since $BC_1C_2 \cdots C_n = A_1 \cdots A_n B$, this follows immediately from (vii);

(ix) verify by direct multiplication of the matrices involved;

x) when $d > 1$ we may use the first part of (ix) with $x$ chosen so that $0 < c - xd < d$ (since $ad - bc = \pm 1$ it is clear that $d$ does not divide $c$); the matrix \[
\begin{pmatrix}
  b & a - xd \\
  d & c - xd
\end{pmatrix}
\] has determinant $\pm 1$ so we can again apply the same part if $c - xd > 1$; if $c - xd = 1$ we may use the second part of (ix) getting the product of 2 matrices when $a - bc = 1$ and the product of 3 matrices when $bc - a = 1$.

\[ P \ i) \quad A_i = \begin{pmatrix}
  1+x & 1 \\
  1 & 1-x
\end{pmatrix} \quad \text{so}
\]

\[ f_i(x) = 1 = q_i(-x), \quad f_i(x) = 1-x = 1+(-x) = f_i(-x); \]
suppose true up to \( n \), then

\[
\prod_{m=1}^{n+1} A_m = \begin{pmatrix} f_n(x) & g_n(x) \\ g_n(-x) & f_n(-x) \end{pmatrix} \begin{pmatrix} 2n+1+x & 2n+1 \\ 2n+1 & 2n+1-x \end{pmatrix}
\]

so

\[
f_{n+1}(x) = (2n+1+x)f_n(x) + (2n+1)g_n(x)
\]

\[
g_{n+1}(x) = (2n+1)f_n(x) + (2n+1-x)g_n(x)
\]

\[
h_{n+1}(x) = (2n+1+x)q_n(-x) + (2n+1)\int f_n(-x)
\]

\[
k_{n+1}(x) = (2n+1)q_n(-x) + (2n+1-x)\int f_n(-x)
\]

clearly \( f_{n+1}(-x) = h_{n+1}(x) \) and \( q_{n+1}(-x) = h_{n+1}(x) \);

\[a) \quad f_{n+1}(x) = (2n+1)(f_n(x) + g_n(x)) + x f_n(x)
\]

\[= \sum_{k=0}^{n} \frac{(2n-k)!}{(n-k)! n!} \frac{(2n+1)!}{k!(n-k+1)!} x^k + \sum_{k=1}^{n+1} \frac{n(n-k)!}{(n-k+1)! (k-1)!} x^k
\]

\[= \frac{(2n+1)!}{n!} + \sum_{k=1}^{n} \frac{(2n-k)!}{(n-k)!(k-1)!} \left\{ \frac{(n+1)(2n-k+1)}{k(n-k+1)} \right\} x^k + x^{n+1}
\]

\[= \sum_{k=0}^{n+1} \frac{(n+1)(2n-k+1)}{(n-k+1)! k!} x^k ;
\]

\[b) \quad g_{n+1}(x) = (2n+1)(f_n(x) + g_n(x)) - x g_n(x)
\]

\[= \sum_{k=0}^{n} \frac{(2n-k)!}{(n-k)! k!} (2n+1)x^k - \sum_{k=1}^{n+1} \frac{(n-k+1)(2n-k)!}{(n-k+1)!(k-1)!} x^k
\]

\[= \frac{(2n+1)!}{n!} + \sum_{k=1}^{n} \frac{(2n-k)!}{(n-k)!(k-1)!} \left\{ \frac{2n+1}{k} - \frac{n-k+1}{n-k+1} \right\} x^k
\]

\[= \sum_{k=0}^{n+1} \frac{(n+1-k)(2n-k+1)}{(n+1-k)! k!} x^k ;
\]
\[(\text{iii-a}) \quad \frac{f_n(x)}{n(n+1)\cdots(2n-1)} \]

\[= \sum_{k=0}^{n} \frac{n(2n-k-1)! \cdot x^k}{n(n+1)\cdots(2n-1)(n-k)! \cdot k!} \quad \text{and, for } k \geq 2,\]

\[= \frac{n(2n-k-1)!}{n(n+1)\cdots(2n-1)(n-k)! \cdot k!},\]

\[= \frac{1}{k!} \prod_{i=0}^{k-1} \frac{n-i}{2n-i-1} < \frac{1}{k!} \cdot \frac{1}{2^{k-1}} ; \quad \text{since} \]

\[\sum_{k=0}^{\infty} \frac{1}{k!} \cdot \frac{1}{2^{k-1}} < \infty, \quad \lim_{n \to \infty} \frac{f_n(x)}{n(n+1)\cdots(2n-1)} = \sum_{k=0}^{\infty} \frac{1}{k!} \left( \frac{x}{2} \right)^k = e^{x/2} ; \]

\[b) \quad \text{same argument as in (a)} ;\]

\[w) \quad \frac{f_n(x)}{h_n(x)} = \frac{f_n(x)}{q_n(x)} = \frac{f_n(x)}{r(n+1)\cdots(2n-1)} = \frac{f_n(x)}{g_n(-x)} \rightarrow \frac{e^{x/2}}{e^{-x/2}} = e^x , \]

and \[\frac{g_n(x)}{r_n(x)} = \frac{g_n(x)}{f_n(-x)} \rightarrow e^x \quad \text{as above} ;\]

thus \(K(A_1A_2\cdots)\) exists and is \(e^x\);
\(v-a\) multiplication on the right side yields the left side:

\[ 6) \begin{bmatrix} 1, k-1, 1, 1, 3k-1, 1, 1, 5k-1, 1, \cdots \end{bmatrix} \]

\[ = K \left\{ \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{k}{1} \end{bmatrix} \begin{bmatrix} \frac{3k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{5k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \right\} \cdots \]

\[ = K \left\{ \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{k}{1} \end{bmatrix} \begin{bmatrix} \frac{k}{1} \end{bmatrix} \begin{bmatrix} \frac{3k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{5k-1}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \right\} \cdots \]

\[ = K \left\{ \begin{bmatrix} \frac{k+1}{k} \end{bmatrix} \begin{bmatrix} \frac{k}{k-1} \end{bmatrix} \begin{bmatrix} 3k+1 \end{bmatrix} \begin{bmatrix} 3 \end{bmatrix} \begin{bmatrix} 5k+1 \end{bmatrix} \begin{bmatrix} 5 \end{bmatrix} \right\} \cdots \]

\[ = K \left\{ \begin{bmatrix} \frac{k}{k} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{3}{k} \end{bmatrix} \begin{bmatrix} \frac{3}{1} \end{bmatrix} \begin{bmatrix} \frac{5}{k} \end{bmatrix} \begin{bmatrix} \frac{5}{1} \end{bmatrix} \right\} \cdots \]

\[ = K \left\{ \begin{bmatrix} \frac{1^+\frac{1}{k}}{1} \end{bmatrix} \begin{bmatrix} \frac{1}{1} \end{bmatrix} \begin{bmatrix} \frac{3}{3} \end{bmatrix} \begin{bmatrix} \frac{3}{3} \end{bmatrix} \begin{bmatrix} \frac{5}{5} \end{bmatrix} \begin{bmatrix} \frac{5}{5} \end{bmatrix} \right\} = e^{1/k} ; \]

we have used I (\(i\)), I (\(v\)), II (\(v-a\)), I (\(iv\)), II (\(iv\)) in order;

c) put \(k=1\) in (6) to obtain

\[ \begin{bmatrix} 1, 0, 1, 1, 2, 1, 1, 4, 1, 1, 6, 1, \cdots \end{bmatrix} \]

\[ = 1 + \frac{1}{0+\begin{bmatrix} 1 \end{bmatrix}} = 1 + \begin{bmatrix} 1, 1, 2, 1, 1, 4, 1, 1, 6, 1, \cdots \end{bmatrix} = \begin{bmatrix} 2, 1, 2, 1, 1, 4, 1, 1, 6, 1, \cdots \end{bmatrix} . \]
24. i) \( C_n = \frac{b_1}{a_1} = \frac{a_1 \cdot 0 - b_1 \cdot (-1)}{a_1 \cdot 1 - b_1 \cdot 0} = \frac{p_1}{q_1} \); \\
\( C_2 = \frac{b_2}{a_2} = \frac{b_1 a_2}{a_1 a_2 - b_2} = \frac{a_2 b_1 - b_2 \cdot 0}{a_2 a_1 - b_2 \cdot 1} = \frac{p_2}{q_2} \);

suppose true for \( n-1 \); then

\[ C_n = \frac{b_1}{a_1} \cdots \frac{b_n}{a_n} = \frac{b_1}{a_1} \cdots \frac{b_{n-1}}{a_{n-1}} - \frac{b_n}{a_n} \]

\[ = \frac{(a_{n-1} - \frac{b_n}{a_n})p_{n-2} - b_{n-1}p_{n-3}}{(a_{n-1} - \frac{b_n}{a_n})q_{n-2} - b_{n-1}q_{n-3}} \]

\[ = \frac{a_n(a_{n-1} p_{n-2} - b_{n-1} p_{n-3}) - b_n p_{n-2}}{a_n(a_{n-1} q_{n-2} - b_{n-1} q_{n-3}) - b_n q_{n-2}} \]

\[ = \frac{a_n p_{n-1} - b_n p_{n-2}}{a_n q_{n-1} - b_n q_{n-2}} = \frac{p_n}{q_n} \; ; \]

ii) \( p_n - p_{n-1} = (a_{n-1}) p_{n-1} - b_n p_{n-2} \)

\( \geq b_n (p_{n-1} - p_{n-2}) \geq \cdots \geq b_0 \cdots b_n \; ; \)

consequently \( p_n \geq p_{n-1} + b_0 \cdots b_n \)

\( \geq \cdots \geq b_0 + b_0 b_1 + \cdots + b_0 \cdots b_n \; ; \)

clearly if \( a_{n-1} = b_n \) for all \( n \) strict equality holds everywhere; if \( a_j > b_j + 1 \) then, for \( n \geq j \),

\( p_j > b_0 + \cdots + b_0 \cdots b_n \); changing all \( p_j \) to \( q_j \)
yields the same result for \( q_n \);
iii) \[ p_{n-1} - p_{-1} q_0 = b_0, \quad p_{1} q_0 - p_{0} q_1 = b_0 b_1 \]
\[ p_n q_{n-1} - p_{n-1} q_n = (a_n q_{n-1} - b_n p_{n-2}) q_{n-1} - p_{n-1} (a_n q_{n-1} - b_n q_{n-2}) \]
\[ = (p_{n-1} q_{n-2} - p_{n-2} q_{n-1}) b_n = b_0 \cdots b_n \]
Dividing by \[ q_{n-1} q_n \] yields the last equality.

iv) \[ q_0 - p_0 = 1 = q_{-1} - p_{-1}, \]
\[ q_1 - p_1 = a_1 - b_1 \geq 1 = q_0 - p_0 \]
Assuming true for \( n-1, n-2 \) we have
\[ q_n - p_n = a_n (q_{n-1} - p_{n-1}) - b_n (q_{n-2} - p_{n-2}) \]
\[ = q_{n-1} - p_{n-1} + (a_{n-1})(q_{n-1} - p_{n-1}) - b_n (q_{n-2} - p_{n-2}) \]
\[ = q_{n-1} - p_{n-1} + b_n \{ (q_{n-1} - p_{n-1}) - (q_{n-2} - p_{n-2}) \} \]
\[ \geq q_{n-1} - p_{n-1} \geq 1 \]
If \( a_{j-1} = b_j \) for \( j \leq n \) we have
\[ q_n - p_n = q_{n-1} - p_{n-1} = \cdots = q_0 - p_0 = 1 \]

v) From (iv), after dividing by \( q_n \), we see \( 1 - \frac{p_n}{q_n} \geq \frac{1}{q_n} \) so \( \frac{p_n}{q_n} \leq 1 - \frac{1}{q_n} < 1 \); from (iii) the sequence \( \left\{ \frac{p_n}{q_n} \right\} \) is monotone increasing.
therefore since this sequence is monotone increasing and bounded above by 1 it must converge to a limit \( \leq 1 \);

if \( a_j > b_j + 1 \) and \( n \geq j \) we have

\[
\frac{p_n}{q_n} = \frac{b_1}{q_1 q_0} + \cdots + \frac{b_n}{q_n q_{n-1}} \\
\leq \frac{q_1 - q_0}{q_1 q_0} + \cdots + \frac{q_n - q_{n-1}}{q_n q_{n-1}} - \left\{ \frac{q_1 - q_{j-1}}{q_j q_{j-1}} - \frac{b_1}{q_j q_{j-1}} \right\}
\]

\[
= \left( \frac{1}{q_0} - \frac{1}{q_1} \right) + \cdots + \left( \frac{1}{q_{n-1}} - \frac{1}{q_n} \right) - \left\{ \frac{q_1 - q_{j-1}}{q_j q_{j-1}} - \frac{b_1}{q_j q_{j-1}} \right\}
\]

\[
= \frac{1}{q_0} - \frac{1}{q_n} - \left\{ \frac{q_1 - q_{j-1}}{q_j q_{j-1}} - \frac{b_1}{q_j q_{j-1}} \right\};
\]

now, since \( \frac{q_1 - q_{j-1}}{q_j q_{j-1}} - \frac{b_1}{q_j q_{j-1}} > 0 \), we have

\[
\lim_{n \to \infty} \frac{p_n}{q_n} \leq \frac{1}{q_0} - \left\{ \frac{q_1 - q_{j-1}}{q_j q_{j-1}} - \frac{b_1}{q_j q_{j-1}} \right\} < 1;
\]

\[\text{vi)} \text{ when } a_n = b_n + 1 \text{ for all } n, \]

\[
\frac{p_n}{q_n} = 1 - \frac{1}{q_n} = 1 - \frac{1}{b_0 + \cdots + b_{n-1}}
\]

and the results follow from this equality.

\[\Pi \ i) \text{ Since } \frac{b_n}{a_n} \text{ is positive and the convergents to } \alpha_n \text{ are monotone increasing (see I (iii)), we know } 0 < \alpha_n;\]
since for each $n$ there is a $j > n$ such that $a_j > b_{j+1}$, we know by I(v) that $\alpha_n < 1$;

\[ \text{ii') for } m > n, \]
\[ \alpha_1 = \lim_m \left\{ \frac{b_1}{a_1} \cdots \frac{b_m}{a_m} \right\} = \lim_m \left\{ \frac{b_1}{a_1} \cdots \frac{b_{n-1}}{a_{n-1} - c_{nm}} \right\} \]
\[ = \frac{b_1}{a_1} \cdots \frac{b_{n-1}}{a_{n-1} - \lim_m c_{nm}} = \frac{b_1}{a_1} \cdots \frac{b_{n-1}}{a_{n-1} - \alpha_n}, \]
where $c_{nm} = \frac{b_n}{a_n} \cdots \frac{b_m}{a_m}$; thus rationality of any $\alpha_j$ implies that of $\alpha_1$ and hence of every $\alpha_j$;

\[ \text{iii') } \alpha_j = \frac{b_j}{a_j - \alpha_{j+1}} \text{ so } \alpha_{j+1} = \frac{ra_j - s_b_j}{r}; \]
by (i'), $0 < \alpha_{j+1} < 1$ so $0 < ra_j - s_b_j < r$;

\[ \text{iv) otherwise, by (iii'), we could construct an infinite strictly monotone decreasing sequence of positive integers}; \]

\[ \text{v) this follows from (iv) if } a_n \geq b_{n+1} \text{ from } n = 1 \text{ on}; \text{ otherwise}, \]
suppose this is true only for \( n \geq m \); then \( \alpha_m \) is irrational, by (v), hence \( \alpha = \frac{b_1}{a_1} \cdots \frac{b_m}{a_{m-1} - \alpha_m} \)

\[
= \frac{(a_{m-1} - \alpha_m) p_{m-2} - b_{m-1} p_{m-3}}{(a_{m-1} - \alpha_m) q_{m-2} - b_{m-1} q_{m-3}},
\]

from which we find

\[
(\alpha_m - \alpha_{m-1}) (p_{m-2} - \alpha q_{m-2}) = b_{m-1} (p_{m-3} - \alpha q_{m-3});
\]

the irrationality of \( \alpha_m - \alpha_{m-1} \) then says, if \( \alpha \)

is rational, \( p_{m-2} - \alpha q_{m-2} = p_{m-3} - \alpha q_{m-3} = 0 \)

which implies the false equality

\[
\alpha = \frac{p_{m-2}}{q_{m-2}} = \frac{p_{m-3}}{q_{m-3}}.
\]

25. i) True for \( n = 2 \); assume true for \( n \),

then

\[
\sum_{k=1}^{n+1} \frac{1}{c_k} = \sum_{k=1}^{n} \frac{1}{c_k} + \frac{1}{c_n} + \frac{1}{c_{n+1}} = \sum_{k=1}^{n} \frac{1}{c_k} + \frac{1}{c_n + \frac{1}{c_{n+1}}}
\]

\[
= \frac{1}{c_1} - \frac{c_1^2}{c_1 + c_2} \cdots \frac{c_n^2}{c_{n-1} + \frac{1}{c_n + \frac{1}{c_{n+1}}}}
\]

\[
= \frac{1}{c_1} - \frac{c_1^2}{c_1 + c_2} \cdots \frac{c_n^2}{c_{n-1} + c_n - \left\{ c_n - \frac{\frac{1}{c_n}}{c_n + \frac{1}{c_{n+1}}} \right\}}
\]

\[
= \frac{1}{c_1} - \frac{c_1^2}{c_1 + c_2} \cdots \frac{c_n^2}{c_{n-1} + c_n - \frac{c_n^2}{c_n + \frac{1}{c_{n+1}}}};
\]
ii) as in (i) after noting that

\[
\frac{c_{n-2}(c_n + c_{n+1})}{c_{n-1} + (c_n + c_{n+1})} = \frac{c_{n-2}c_n}{c_{n-1} + c_n} - \frac{\frac{c_{n-1}c_{n+1}}{C_n + C_{n+1}}}{C_n + C_{n+1}}
\]

iii) clear;

w) using (i),

\[
q = 2! - \frac{2!^2}{2! - 3! - \frac{3!^2}{-3! + 4! - \frac{4!^2}{4! - 5! - \frac{5!^2}{-5! + 6! - \cdots}}}}
\]

\[
= 2 + \frac{2}{2 + \frac{3}{3 + \frac{4}{4 + \frac{5}{5 + \frac{6}{6 + \cdots}}}}}
\]

\[
= 2 + \frac{1}{1 + \frac{3}{2 + \frac{2 \cdot 4}{2 \cdot 3 + \frac{5}{4 + \frac{5}{5 + \frac{6}{6 + \cdots}}}}}}
\]

\[
= 2 + \frac{1}{1 + \frac{1}{2 + \frac{2 \cdot 4}{3 \cdot 4 + \frac{3 \cdot 5}{3 \cdot 4 + \frac{6}{5 + \frac{6}{6 + \cdots}}}}}}
\]

\[
= 2 + \frac{1}{1 + \frac{2}{3 + \frac{3}{4 + \frac{4}{4 + \cdots}}}}
\]
v) using (ii)

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots$$

$$= \frac{1}{1 - \frac{1}{3} - \frac{1}{5} + \frac{1}{7} - \cdots}$$

$$= \frac{1}{1 + \frac{1}{2 + \frac{3^2}{2 + \frac{5^2}{2 + \frac{7^2}{2 + \cdots}}}}}$$

26. i) for each fixed $x$

$$\frac{x^{2n}}{2^{2n}n! \cdot m(m+1)\cdots(m+n-1)} \cdot \frac{2^{2n-2}(n-1)! \cdot m(m+1)\cdots(m+n-2)}{x^{2n-2}}$$

$$= \frac{x^2}{2^{2n}(m+n-1)} < 1$$

for $n$ sufficiently large;

ii) the given assertion is equivalent to

$$\frac{f_{m+1}(x) - \frac{x^2}{2^m m(m+1)} f_{m+2}(x)}{f_{m+1}(x)} = f_m(x)$$
the left side equals

\[
1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! (m+1) \cdots (m+k)} - \frac{x^2}{2^2 m (m+1)} - \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! (m+2) \cdots (m+k+1)}
\]

\[
= 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! (m+1) \cdots (m+k)} - \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! (m+1) \cdots (m+k+1)}
\]

\[
= 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} (k-1)! (m+1) \cdots (m+k)} = \int_{m}^{x}
\]

the 2nd equality follows immediately from

the 1st;

\[
iii) \quad f_{1/2}(x) = 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! \frac{1}{2} \cdot \frac{3}{2} \cdots \frac{2k-1}{2}}
\]

\[
= 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{(2k)!} = \sum_{k=0}^{\infty} \frac{(-1)^k x^{2^k}}{(2k)!} = \cos x ;
\]

\[
f_{3/2}(x) = 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{2^{2^k} k! \frac{3}{2} \cdots \frac{2k+1}{2}}
\]

\[
= 1 + \sum_{k=1}^{\infty} \frac{(-1)^k x^{2^k}}{(2k+1)!} = \sum_{k=0}^{\infty} \frac{(-1)^k x^{2^k}}{(2k+1)!} = \frac{\sin x}{x} ;
\]

thus \[\frac{f_{3/2}(x)}{f_{1/2}(x)} = \frac{\tan x}{x} ;\]
iv) in (iii) put \( \pi = \frac{\pi}{4} \) to obtain (successively)

\[
\frac{4}{\pi} = \frac{1}{1} - \frac{(\pi/4)^2}{3} - \frac{(\pi/4)^2}{5} - \frac{(\pi/4)^2}{7} - \ldots
\]

\[
1 = \frac{\pi/4}{1} - \frac{(\pi/4)^2}{3} - \frac{(\pi/4)^2}{5} - \frac{(\pi/4)^2}{7} - \ldots
\]

\[
= \frac{m}{n} - \frac{m^2}{3n} - \frac{m^2}{5n} - \frac{m^2}{7n} - \ldots \frac{m^2}{(2k-1)n} - \ldots;
\]

the right hand side of this last expression satisfies, for \( k \) sufficiently large, the condition \( (2k-1)n \geq m^2 + 1 \) and hence by

\#24 \( \Pi \) (v) is irrational.

27. I. The number of integral polynomials of degree \( n \) is countable as are the zeros of such polynomials; hence for each \( n \) there are at most countably many algebraic numbers of degree \( n \); since this means the set of all algebraic numbers is countable and since the set of real numbers is uncountable there exist transcendental numbers;
\( i \) one merely divides \( f(x) \) by \( x - \alpha \) to obtain \( g(x) \), which, being of degree \( n - 1 \), does not have \( \alpha \) as a zero;

\( ii) \) since \( g \) is continuous and \( g(\alpha) \neq 0 \) this is immediate;

\( iii) \) choose integers \( a, b \) (\( b > 0 \)) such that \( \alpha - \delta \leq \frac{a}{b} \leq \alpha + \delta \); then if \( M \) is the maximum absolute value of \( g \) on \([\alpha - \delta, \alpha + \delta]\)
we have
\[
|\alpha - \frac{a}{b}| = \left| \frac{f\left(\frac{a}{b}\right)}{g\left(\frac{a}{b}\right)} \right| \geq \left| \frac{f\left(\frac{a}{b}\right)}{M} \right| \geq \frac{|f\left(\frac{a}{b}\right)| b^n}{M b^n};
\]
now \( f\left(\frac{a}{b}\right) b^n \) is an integer and is not zero since if so \( \alpha \) would not be algebraic of degree \( n \); hence \( |\alpha - \frac{a}{b}| \geq \frac{1}{M b^n} \);

\( iv) \) choose \( c = \min \left\{ \frac{\delta}{2}, \frac{1}{M+1} \right\} \); then for \( \frac{a}{b} \) outside \([\alpha - \delta, \alpha + \delta]\),
\[
|\alpha - \frac{a}{b}| > \delta > c \geq \frac{c}{b^n}
\]
and for \( \frac{a}{b} \) inside \([\alpha - \delta, \alpha + \delta]\),

\[
|\alpha - \frac{a}{b}| \geq \frac{1}{M b^n} > \frac{1}{(M+1)b^n} \geq \frac{c}{b^n}.
\]

III 1) According to II (iv) if \( \alpha \) were rational there would be a positive constant \( c \) such that \( |\alpha - \frac{a}{b}| \geq \frac{c}{b^n} \) for all integers \( a, b \) \((b > 0)\); but with \( a = 10^2 \sum_{m=0}^{n} 10^{-2^m} \), \( b = 10^2 \)
we have

\[
|\alpha - \frac{a}{b}| = \sum_{m=n+1}^{\infty} 10^{-2^m} < 10^{-2^{n+1}} + 1 = \frac{10^{-2^{n+1}}}{b}
\]

and this, for \( n \) sufficiently large, will not be \( \geq \frac{c}{b^n} \) for any positive \( c \);

an alternative proof is to observe that the decimal expansion of \( \alpha \) has infinitely many non-zero digits as well as arbitrarily long blocks of consecutive 0's, hence can not be periodic;

\[\text{ii) for each } n, \text{ by II (v) if } \alpha \text{ is Liouville then } \alpha \text{ is not algebraic of degree } n;\]
Let $n$ be a positive integer and $c$ be a positive constant; choose $k > n$ such that $M \cdot 10^{-k! + 1} < c$ and put $a = 10^{\frac{k!}{k!}} \sum_{m=0}^{\infty} a_m 10^{-m!}$, $b = 10^{\frac{k!}{k!}}$; then
\[
|\alpha - \frac{a}{b}| = |\sum_{m=k+1}^{\infty} a_m 10^{-m!}| \leq M \cdot 10^{-(k+1)! + 1} = \frac{M \cdot 10^{-k! + 1}}{(10^{k!})^k} < \frac{c}{b^k} < \frac{c}{b^n}
\]
thus by (ii) $\alpha$ is transcendental.

Let $n$ and $c$ be given and choose $k > n$ so that $\frac{1}{q_k} < c$; then with $a = p_k$, $b = q_k$ we have
\[
|\alpha - \frac{a}{b}| = |\alpha - \frac{p_k}{q_k}| < \frac{1}{q_k q_{k+1}} = \frac{1}{q_k (a_{k+1} q_k + q_{k+1})}
\]
\[
< \frac{1}{a_{k+1} q_k^2} < \frac{1}{q_k^{k+1}} < \frac{c}{q_k^k} = \frac{c}{b^k} < \frac{c}{b^n}
\]
and the result follows from III (ii);

Take $a_k = 2^{k!}$, giving
\[
[1, 2, 2^2, 2^6, 2^{24}, 2^{120}, ...]
\]
iii) we need to show \( a_{k+1} > (2^k a_1 \cdots a_k)^{k-1} \) implies \( a_{k+1} > q_k \) (for \( k \geq 1 \)) and this, in turn, would follow from \( 2^k a_1 \cdots a_k > q_k \) (for \( k \geq 1 \)); for \( k=1 \), \( 2a_1 > q_1 = a_1 \); if true for \( k \) then \( 2^{k+1} a_1 \cdots a_{k+1} > 2 a_{k+1} q_k > a_{k+1} q_k + q_{k+1} = q_{k+1} \).

28. i) The probability that an arbitrary \( x \) in \([0,1]\) is irrational is 1 and that probability is also the indicated sum since every \( x \) has exactly 1 integral value for \( a_n(x) \); similarly the set of irrational \( x \) with given \( a_1, \cdots, a_{n-1} \) is the same as the set of irrational \( x \) with given \( a_1, \cdots, a_{n-1} \) and \( a_n(x) \) a positive integer;

ii) the set of \( x \) with \( a_1(x) = k \) is just the set of \( x \) satisfying \( \frac{1}{k+1} < x < \frac{1}{k} \) and the probability of \( x \) being in here is just \( \frac{1}{k} - \frac{1}{k+1} = \frac{1}{k(k+1)} \).
iii) The set of \( x \) with \( a_1(x) = n \) and \( a_2(x) = k \) is just the set of \( x \) satisfying

\[
\frac{1}{n + \frac{1}{k}} < x = \frac{1}{n + \frac{1}{k + \frac{1}{k+2}}} < \frac{1}{n + \frac{1}{k + 1}} ;
\]

thus the probability of \( a_2(x) = k \) is just

\[
\sum_{n=1}^{\infty} \left( \frac{1}{n + \frac{1}{k+1}} - \frac{1}{n + \frac{1}{k}} \right) = P_{1K} \sum_{n=1}^{\infty} \frac{1}{(n + \frac{1}{k})(n + \frac{1}{k+1})} = P_{1K} \sum_{n=1}^{\infty} \left( \frac{1}{n^2} + \sum_{n=1}^{\infty} \frac{1}{n^2(n + \frac{1}{k})(n + \frac{1}{k+1})} \right)
\]

\[
= \frac{\pi^2}{6k(k+1)} \left( 1 - \frac{\pi^2}{6} \sum_{n=1}^{\infty} \frac{1}{n^2(n + \frac{1}{k})(n + \frac{1}{k+1})} \right).
\]

where \( \epsilon_k = \frac{\pi^2}{6k(k+1)} \sum_{n=1}^{\infty} \frac{1}{n^2(n + \frac{1}{k})(n + \frac{1}{k+1})} < \frac{\pi^2}{6k^2} \sum_{n=1}^{\infty} \frac{2}{n^3} \rightarrow 0 \text{ as } k \rightarrow \infty ;
\]

iv) for \( k \geq 2 \),

\[
P_{2K} = P_{1K} \sum_{n=1}^{\infty} \frac{1}{(n + \frac{1}{k})(n + \frac{1}{k+1})} \times P_{1K} \sum_{n=1}^{\infty} \frac{1}{(n + \frac{1}{k})(n + \frac{1}{k+1})} > P_{1K} \sum_{n=1}^{\infty} \frac{1}{n(n+1)} = P_{1K} ;
\]

\[
P_{21} = P_{11} \sum_{n=1}^{\infty} \frac{1}{(n+1)(n + \frac{1}{2})} < P_{11} \sum_{n=1}^{\infty} \frac{1}{n(n+1)} = P_{11} .
\]
ii) By the relevant lie between \([0, a_1, \ldots, a_{n-1}, k] \) and \([0, a_1, \ldots, a_{n-1}, k+1]\); thus

\[
P(a_1, \ldots, a_{n-1}, k) = \left| \frac{kp_{n-1} + p_{n-2}}{kq_{n-1} + q_{n-2}} - \frac{(k+1)p_{n-1} + p_{n-2}}{(k+1)q_{n-1} + q_{n-2}} \right|
\]

\[
= \frac{\left| p_{n-2} q_{n-1} - p_{n-1} q_{n-2} \right|}{(kq_{n-1} + q_{n-2})(k+1)q_{n-1} + q_{n-2})}
\]

\[
= 1/q_{n-1}^2 (k + q_{n-2}/q_{n-1})(k + 1 + q_{n-2}/q_{n-1});
\]

iii) the middle (equality) follows directly from (i); the inequalities follow from the fact that \(\frac{k+x}{k+2+x}\) is strictly increasing on \([0, 1]\);

\[
\text{iii})\quad \text{the middle expression is}\quad \frac{(1+x)(2+x)}{(k+x)(k+1+x)},\quad \text{with} \quad x = \frac{q_{n-2}}{q_{n-1}},\quad \text{and is strictly increasing on} \quad [0, 1];
\]

iv) summing (iii) over all positive \(k\) yields the result when one takes account of I(i);

v) multiply the equality in (iii) term by term by the (reciprocal) inequality in (iv),
i.e. by $\frac{1}{3} < \frac{P(a_1, \ldots, a_{n+1})}{P(a_1, \ldots, a_n)} < \frac{1}{2}$ and one obtains the desired inequality when one observes that

$$P(a_1, \ldots, a_{n-1}, k) = P(a_1, \ldots, a_{n-1}) P_n k.$$ 

III i) $\sum_{k=1}^{M} P_1 k = \sum_{k=1}^{M} \frac{1}{k(k+1)} = \sum_{k=1}^{M} \left( \frac{1}{k} - \frac{1}{k+1} \right) = 1 - \frac{1}{M+1} = \frac{M}{M+1}$;

ii) $\sum_{k=1}^{M} P(a_1, \ldots, a_{n-1}, k) = P(a_1, \ldots, a_{n-1}) - \sum_{k=M+1}^{\infty} P(a_1, \ldots, a_{n-1}, k) = P(a_1, \ldots, a_{n-1}) - \sum_{k=M+1}^{\infty} \frac{2}{3} \frac{1}{k(k+1)} = P(a_1, \ldots, a_{n-1})(1 - \frac{2}{3(M+1)})$;

iii) using (ii) iteratively we have

$$\sum_{1 \leq a_1 \leq M} \sum_{1 \leq j \leq n} P(a_1, \ldots, a_n) = \sum_{a_1=1}^{M} \cdots \sum_{a_{n-1}=1}^{M} \sum_{k=1}^{M} P(a_1, \ldots, a_{n-1}, k) < \alpha \sum_{a_1=1}^{M} \cdots \sum_{a_{n-1}=1}^{M} P(a_1, \ldots, a_{n-1}) < \alpha^2 \sum_{a_1=1}^{M} \cdots \sum_{a_{n-2}=1}^{M} P(a_1, \ldots, a_{n-2}) < \cdots < \alpha^{n-1} \sum_{a_1=1}^{M} P(a_1) = \alpha^{n-1} \frac{M}{M+1}.$$
iv) by (iii), for each \( M \) the probability that the partial quotients do not exceed \( M \) is 0; thus the probability that they are bounded is also 0.

\[ \nabla \text{i)} \quad \text{Sum II (v) for } k \geq \varphi(t) \text{ to obtain } \]
\[ \frac{2}{3A} < \sum_{k \geq \varphi(t)} p(a_1, \ldots, a_{k-1}, k) < \frac{3}{A+1}, \text{ where } A \text{ is an integer satisfying } A-1 < \varphi(t) \leq A; \]
now \[ \frac{2}{3(\varphi(t)+1)} < \frac{2}{3A} \text{ and } \frac{3}{A+1} \leq \frac{3}{\varphi(t)+1} \text{ and the result follows; } \]

\[ \text{ii) this follows immediately from } (i) \land I(i); \]

\[ \text{iii) the result in (ii) may be written } \]
\[ p(a_1, \ldots, a_{t-1}) \left(1 - \frac{3}{\varphi(t)+1}\right) < \sum_{1 \leq a_t < \varphi(t)} p(a_1, \ldots, a_{t-1}, a_t) < p(a_1, \ldots, a_{t-1}) \left(1 - \frac{2}{3(\varphi(t)+1)}\right), t > N; \]
iteration of this result leads successively to
\[ p(a_1, \ldots, a_{t-2}) \left(1 - \frac{3}{\varphi(t-1)+1}\right) \left(1 - \frac{3}{\varphi(t)+1}\right) \]

\[ < \sum_{1 \leq a_{t-1} < \varphi(t-1)} \sum_{1 \leq a_t < \varphi(t)} p(a_1, \ldots, a_t) \]

\[ < p(a_1, \ldots, a_{t-2}) \left(1 - \frac{2}{3(\varphi(t-1)+1)}\right) \left(1 - \frac{2}{3(\varphi(t)+1)}\right), \]

\[ \ldots \]

\[ p(a_1, \ldots, a_N) \prod_{j=N+1}^{t} \left(1 - \frac{3}{\varphi(j)+1}\right) \]

\[ < \sum_{1 \leq a_{N+1} < \varphi(N+1)} \sum_{1 \leq a_t < \varphi(t)} p(a_1, \ldots, a_t) \]

\[ < p(a_1, \ldots, a_N) \prod_{j=N+1}^{t} \left(1 - \frac{2}{3(\varphi(j)+1)}\right); \]

(iii) the series \( \sum \frac{1}{\varphi(n)} \), \( \sum \frac{1}{\varphi(n)+1} \) converge or diverge together; also the series \( \sum \frac{1}{\varphi(n)+1} \) and the product \( \prod \left(1 - \frac{2}{3(\varphi(n)+1)}\right) \) converge or diverge together; thus when \( \sum \frac{1}{\varphi(n)} \) diverges so also does \( \sum \frac{2}{3(\varphi(n)+1)} \) and, since the terms are all positive and \(<1\), this implies \( \prod \left(1 - \frac{2}{3(\varphi(n)+1)}\right) \) diverges to \(0\); thus by the left inequality in (iii) the probability that a random \(x\) with first \(N+1\) partial quotients
fixed satisfies $a_n(x) < \varphi(n)$ for $n > N$ is $0$; since this is true for all choices of $a_1, \ldots, a_N$, and there are only countably many such choices the result follows; when $\Sigma \frac{1}{\varphi(n)}$ converges so also do $\Sigma \frac{1}{3(\varphi(n)+1)}$ and $\Pi (1 - \frac{1}{3(\varphi(n)+1)})$; further, given $\epsilon > 0$ there is an $N$ such that for $t > N$ the inequality

$$1 - \epsilon < \prod_{j=N}^{t} (1 - \frac{1}{\varphi(j)+1}) < 1$$

holds (otherwise the product would diverge to $0$); but then, by the inequality in (iii),

$$(1 - \epsilon) p(a_1, \ldots, a_N) < \Sigma p(a_1, \ldots, a_t) < p(a_1, \ldots, a_N)$$

and, by summing

$$1 - \epsilon < \Sigma \cdots \Sigma_{a_N} \Sigma_{a_N} \cdots \Sigma_{a_N} p(a_1, \ldots, a_t) < 1$$

and the result follows by observing that this is true for each $\epsilon > 0$. 

1. i) For \(1 \leq s < t \leq p_j\) we see that all prime factors of \(N_t - N_s = (t-s)p_1 \cdots p_{i-1}\), are smaller than \(p_j\); consequently each of \(p_1, \ldots, p_n\) divides at most one of \(N_s\) and \(N_t\);

ii) since \(p_{n-1} > 2\) we may clearly take \(j = n - 1\);

iii) each of the \(n-i+1\) primes \(p_i, \ldots, p_n\) divides at most one of the \(p_i\) numbers \(t p_1 \cdots p_{i-1}, 1 \leq t \leq p_i\); thus, since \(p_i > n - i + 1\), there must be one of these numbers divisible by none of the primes \(p_i, \ldots, p_n\); since, also, none of the primes \(p_i, \ldots, p_{i-1}\) divides any of the numbers the conclusion follows;

iv) if \(i \leq 4\) then \(72 \geq p_i > n - i + 1 > n - 3\) so \(n < 10\); hence \(i > 4\) by our hypothesis; for
\[ i = 5, \ p_{i-1} - 2 = 7 - 2 = 5 = i \ so \ p_{i-1} - 2 \geq i; \] if this last inequality is true for \( i = j \) then
\[ p_j - 2 \geq p_{j-1} \geq j + 2 > j + 1 \]
so it is also true for \( i = j + 1 \); consequently
\[ p_{i-1} - 2 \geq i \] for all \( i \geq 5 \); now, using the minimal property of \( i \),
\[ i \leq p_{i-1} - 2 \leq n - (i - 1) + 1 - 2 < n - i + 1 \]
so the number of factors in \( p_1 \cdots p_i \) is smaller than the number of factors in \( p_{i+1} \cdots p_n \); the desired inequality follows from the fact that \( p_1 < p_{i+1}, p_2 < p_{i+2}, \ldots, p_i < p_{2i} \);

v) by (iii), \( p_{n+1} < p_1 \cdots p_i \) so, using (iv), \( p_{n+1}^2 < p_1 \cdots p_n \).

2. i) Since \( j = k \) we clearly have \( p_j^2 \leq p_k^2 \leq n \) and, since \( p_j \) does not divide \( n \) we must have \( p_j^2 < n, (p_j^2, n) = 1 \);

ii) by (i), no \( p_i \) with \( j = k \) can fail to divide \( n \); consequently \( p_1 \cdots p_k | n \) and, therefore, \( p_1 \cdots p_k \leq n \);
iii) If there is no composite integer \(< n\) and prime to \(n\) then, by (ii), \(p_\ldots p_r \leq n\); since \(n > 49\) and \(p_k^2 \leq n < p_{k+1}^2\), we see that \(k \geq 4\); therefore, by \(\#1(v)\), \(p_k^2 < p_\ldots p_r \leq n < p_{k+1}^2\), which is a contradiction;

iv) by (iii) such an integer must be \(< 49\); direct checking of the integers from 30 to 48 shows 30 to be the largest integer with the stated property.

3. By \(\#2(iv)\), if \(n > 30\) there are integers \(a, b\) satisfying
\[1 < a \leq b, \quad ab < n, \quad (ab, n) = 1;\]
now \(a < \sqrt{n}\) and \(a \nmid n\); this shows no such integer is larger than 30; direct checking of the integers from 24 to 30 shows 24 to be the largest integer with the stated property.
4. i) The canonical factorization of \( n \) has no primes other than \( p_1, \ldots, p_j \); hence \( n = p_1^{\alpha_1} \cdots p_j^{\alpha_j} \) where the \( \alpha_j \geq 0 \); since each positive integer is of the form \( 2t + e \), where \( e = 0 \) or \( 1 \), the conclusion follows;

ii) in (i) the number of possible \( m \) is \( \leq \sqrt{n} \) and the number of possible \( p_1^{e_1} \cdots p_j^{e_j} \) is \( 2^j \); hence \( N_j(n) \leq \sqrt{n} 2^j \);

iii) put \( j = \pi(n) \) in (ii) to obtain
\[
N_j(n) = N_{\pi(n)}(n) \leq \sqrt{n} \ 2^{\pi(n)};
\]
now take natural logs of both sides after dividing by \( \sqrt{n} \); since \( \ln n / 2 \ln 2 \to \infty \) as \( n \to \infty \) the number of primes is infinite;

iv) in (iii) replace each \( n \) by \( p_n \) to obtain
\[
n = \pi(p_n) \geq \frac{\ln p_n}{2 \ln 2};
\]
thus, \( p_n \leq 4^n \); \( p_n \neq 4^n \) so the conclusion follows;
v) if the series converged there would be a $j$ such that $\sum_{n \geq j} \frac{1}{p_n} < \frac{1}{2}$; then

$$2\sqrt{\kappa} \geq N_j(x) \geq x - \sum_{n \geq j} \frac{x}{p_n} > \frac{x}{2}$$

and, therefore,

$$\sqrt{\kappa} < 2^{j+1} \text{ for all } x$$

this is clearly false so the given series converges.

5. If $k$ is composite and $3 \leq k \leq \lceil x \rceil$ then $\sin \frac{k\pi}{j}$ is 0 for some $j$, $2 \leq j \leq k-1$, so the $k^{th}$ term in the right hand sum is 0; if $k$ is prime in the same range then $1 - \left( \sin \frac{k\pi}{j} \right)^2$ is always $< 1$ so its $m^{th}$ power $\to 0$ as $m \to \infty$ and the $k^{th}$ term in the right hand sum is 1; the summand $1$ counts the prime 2.

6. For fixed $n$ if $s$ is larger than the largest exponent in the prime factorization of $n$ and if $m \geq \Theta(n)$ then $\frac{\zeta(1-s)n}{j}$ is an integer when $j \geq m$ and is not an integer for $0 \leq j < \Theta(n)$; thus
for \( s \) and \( m \) so chosen,

\[
\lim_{k \to \infty} \sum_{j=0}^{\infty} \left( 1 - (\cos \left( \frac{(j+1)\pi}{n} \right))^2 \right) = \lim_{n \to \infty} \sum_{j=0}^{n-1} \left( 1 - (\cos \left( \frac{(j+1)\pi}{n} \right))^2 \right) = O(n);
\]

therefore, the triple limit as stated is just \( O(n) \).

7. i) This follows, using \( \# \) 4 (iv), by comparison with \( \sum_{m=2}^{\infty} \left( \frac{4}{10} \right)^m \), which is a convergent geometric series;

ii) put

\[
A_t = 10^{\frac{t(t-1)}{2}} \sum_{m=1}^{t-1} m \cdot 10^{-\frac{m(m+1)}{2}},
\]

\[
B_t = 10^{\frac{t(t-1)}{2}} \sum_{m=t}^{\infty} m \cdot 10^{-\frac{m(m+1)}{2}}
\]

so that

\[
10^{\frac{t(t-1)}{2}} \beta_o = A_t + B_t;
\]

clearly \( A_t \) is an integer and \( 0 < B_t = \sum_{j=0}^{\infty} 10^{-\frac{(t+j)(t+j+1)}{2}} \leq \sum_{j=0}^{\infty} \left( \frac{4}{10} \right)^{t+j} = \frac{2}{3} \left( \frac{4}{10} \right)^{t-1} < 1 \)

for \( t \geq 1 \); thus

\[
\left[ 10^{\frac{t(t-1)}{2}} \beta_o \right] - 10^n \left[ 10^{\frac{n(n+1)}{2}} \beta_o \right] = A_{n+1} - 10^n A_n = 10^{\frac{n(n+1)}{2}} \sum_{m=1}^{n} m \cdot 10^{-\frac{m(m+1)}{2}} - 10^{\frac{n(n+1)}{2}} \sum_{m=1}^{n+1} m \cdot 10^{-\frac{m(m+1)}{2}} = p_n.
\]
8. i, ii) The proof is virtually the same as that given for #7.

9. i) Put \( f(n) = 10^{\frac{\log a^n}{1 + 2}} \) (base 10 logarithm); then (a) is clearly true; for (b) note that, when \( v > n \),
\[
a_v \frac{f(n)}{f(v)} = a_v 10^{\frac{\log a^n}{f(n+1)}} \leq 10^{\frac{\log a^n}{f(n+1)}} \cdot a_v \\
= 10^{\frac{\log a^n}{f(n+1)}} < 10^{-2(v-n) + 1}
\]
and therefore,
\[
\sum_{v=n+1}^{\infty} a_v \frac{f(n)}{f(v)} < \sum_{v=n+1}^{\infty} 10^{-2(v-n) + 1} < 1
\]

ii) \[
[f(t) \alpha] = \sum_{v=1}^{t} a_v \frac{f(t)}{f(v)} + \left[ \sum_{v=t+1}^{\infty} a_v \frac{f(t)}{f(v)} \right]
\]
so
\[
[f(n) \alpha] \frac{f(n)}{f(n-1)} f(n-1) \alpha] = \sum_{v=1}^{n} a_v \frac{f(n)}{f(v)} - \frac{f(n)}{f(n-1)} \sum_{v=1}^{n-1} a_v \frac{f(n-1)}{f(v)}
\]
\[
= a_n
\]

iii) for #7 put \( a_v = p_v \), \( f(n) = 10^{\frac{n(n+1)}{2}} \); for #8 put \( a_v = p_v \), \( f(n) = 10^{2^n} \).
10. i) This follows immediately from
\[
\binom{2n}{n} = \left\{ \frac{2n(2n-2) \cdots 2}{n!} \right\} \left\{ \frac{(2n-1)(2n-3) \cdots 1}{n!} \right\}
= 2^n \left( 2 - \frac{1}{n} \right) \left( 2 - \frac{1}{n-1} \right) \cdots \left( 2 - \frac{1}{1} \right);
\]

ii) by IV #24, the highest power of \( p \) in \( \binom{2n}{n} \) is
\[
\sum_{j=1}^{t_p} \left\{ \left\lfloor \frac{2n}{p^j} \right\rfloor \right\} - 2 \left\lfloor \frac{n}{p^j} \right\rfloor,
\]
which, by IV #13, is \( \leq t_p \); this shows \( \binom{2n}{n} \) divides \( \prod_{p \leq 2n} p^{t_p} \); the other division is clear since no prime \( p \), \( n < p \leq 2n \), is canceled from the numerator of \( \binom{2n}{n} = \frac{(2n)!}{n!n!} \) when one reduces this expression to an integer.

iii-a, b) immediate from (i) and (ii);

iv) \( \sum_{p \leq x} \ln p \geq \sum_{\sqrt{x} < p \leq x} \ln p \geq \frac{x}{2} (\pi(x) - \sqrt{x}) \ln x \) and the rest is immediate;

v) from (iii-a) we see \( 2^n < (2n)^{\pi(2n)} \) and, taking logs, this yields \( \pi(2n) > \frac{n \ln 2}{\ln 2n} \); now
let \( x \geq 2 \) and suppose \( 2n \leq x < 2n + 2 \); then

\[
\pi(x) \geq \pi(2n) \geq \frac{n \ln n}{\ln 2n} > \frac{x^{\frac{\ln x}{\ln 2}}}{\ln x} = \left( \frac{1}{2} - \frac{1}{x} \right) \ln 2 \frac{x}{\ln x}
\]

\[
\geq \frac{\ln 2}{6} \cdot \frac{x}{\ln x} \quad \text{for} \quad x \geq 3;
\]

for \( 2 \leq x \leq 3 \), \( \pi(x) \geq 1 > \frac{\ln 2}{3} \cdot \frac{2}{\ln 2} \geq \frac{\ln 2}{3} \cdot \frac{x}{\ln x} \),

therefore one may take \( A = \frac{\ln 2}{6} \);

\[\text{vi)} \quad \text{from \((iii-6)\),}\quad \sum_{p \leq 2n} \ln p < 2n \ln 2 \quad \text{so} \quad \sum_{p \leq 2n} \ln p < 2n \ln 2 + \sum_{p \leq 2n} \ln p; \quad \text{putting} \quad n = 2^{k-1} \quad \text{and repeatedly using this last inequality we obtain} \quad \sum_{P \leq 2} \ln p < 2^k \ln 2 + \sum_{P \leq 2^{k-1}} \ln p < \cdots < 2^k \ln 2 + 2^{k-1} \ln 2 + \cdots + 2 \ln 2 < 2^{k+1};\]

\[\text{vii)} \quad \text{let} \quad 2^{k-1} \leq x < 2^k; \quad \text{then} \quad \sum_{P \leq x} \ln p \leq \sum_{P \leq 2^k} \ln p < 2^{k+1} \leq 4x;\]

\[\text{viii)} \quad \text{from \((vi)\) and \((vii)\),} \quad \pi(x) \leq \frac{2}{\ln x} \sum_{P \leq x} \ln p + \sqrt{x} \leq 2A \frac{x}{\ln x} + \sqrt{x} < (2A + 1) \frac{x}{\ln x}, \quad \text{for} \quad x \quad \text{sufficiently large}; \quad \text{but for bounded} \quad x \quad \text{there is clearly a constant} \quad B \quad \text{for which}\]
\[ \pi(x) < B \frac{x}{\ln x} \] since \( \frac{x}{\ln x} \) for \( x \geq 2 \) is bounded away from 0; the conclusion follows;

iv) immediate from (v) and (viii).

ii. i) Taking logs in the Chebyshev inequality we have

\[ \ln A + \ln x - \ln \ln x < \ln \pi(x) < \ln B + \ln x - \ln \ln x \]

and dividing by \( \ln x \) yields

\[ 1 + \frac{\ln A - \ln \ln x}{\ln x} < \frac{\ln \pi(x)}{\ln x} < 1 + \frac{\ln B - \ln \ln x}{\ln x} ; \]

the conclusion follows from the fact that the left and right quotients tend to 0 as \( x \to \infty \);

ii) multiply the Chebyshev inequality term by term with the inequality in (i);

iii) put \( x = p_n \) in (ii);
iv) from (iii) it is immediate that
\[ \frac{n \ln n}{B(1+\varepsilon)} < p_n < \frac{n \ln n}{A(1-\varepsilon)} ; \]

v) comparison with the series \( \sum_{n=2}^{\infty} \frac{1}{(n \ln n)^\alpha} \)
yields the result.

12. i) Since \( \left( \begin{array}{c} 2n-1 \\ n \end{array} \right) = \frac{(2n-1)(2n-2) \cdots (2n-(n-1))}{n!} \)
is an integer and no prime between \( n \) and \( 2n \)
gets canceled in the division the left inequality
is clear; now
\[ (1+1)^{2n-1} = \sum_{j=0}^{2n-1} \left( \begin{array}{c} 2n-1 \\ j \end{array} \right) > \left( \begin{array}{c} 2n-1 \\ n-1 \end{array} \right) + \left( \begin{array}{c} 2n-1 \\ n \end{array} \right) = 2 \left( \begin{array}{c} 2n-1 \\ n \end{array} \right) \]
so \( \left( \begin{array}{c} 2n-1 \\ n \end{array} \right) < \frac{1}{2} \cdot 2^{2n-1} = (2^2)^{n-1} = 4^{n-1} ; \)

ii) it suffices to prove the statement for
integral \( x \); for \( x = 2 \), \( x = 3 \) it is clearly correct;
supposing its truth up to and including \( n - 1 \) we
have, for \( n \) even, \( \prod_{p \leq n} p = \prod_{p \leq n-1} p < 4^{n-1} < 4^n \) and,
for \( n \) odd (say \( n = 2k+1 \)),
\[ \prod_{p \leq n} p = (\prod_{p \leq k+1} p) \prod_{k+1} p < 4^{k+1} \cdot 4^k = 4^n ; \]
(iii) \( \binom{2n}{n} = \frac{2n(2n-1)\ldots(n+1)}{n!} \) and, since \( p \leq n < 2p \leq 2n < 3p \), we see that \( p \), but not \( p^2 \), divides the numerator and \( p \) divides the denominator, thus \( p \) does not divide the quotient.

w-a) we prove the left inequality by induction, it being clearly true for \( n = 2 \); assume true for \( n \); then

\[
\binom{2n+2}{n+1} = \frac{(2n+2)(2n+1)}{(n+1)^2} \binom{2n}{n} > 2 \cdot \frac{2n+1}{n+1} \cdot \frac{4n}{2\sqrt{n}} = \frac{4^{n+1}}{2\sqrt{n+1}^2} \frac{2n+1}{2\sqrt{n+1}} > \frac{4^{n+1}}{2\sqrt{n+1}}
\]

b) for the right inequality note that

\[
\binom{2n}{n} \leq \left( \prod_{p \leq \sqrt{2n}} \frac{(2n)!}{p!} \right) \prod_{p \leq \frac{n}{2}} \binom{2n}{n} < \left( \frac{2n}{n} \right)^{\frac{1}{2\sqrt{n}}} 4^{\frac{n}{3}} \binom{2n}{n};
\]

v) by (iv), \( \binom{2n}{n} > 1 \) when \( 4^{\frac{n}{3}} > 2\sqrt{n} \left( \frac{2n}{n} \right)^{\frac{1}{2\sqrt{n}}} \); raising both sides to the 6th power yields the desired result.

vi) using the binomial theorem we note

\[
2n = \left( \sqrt{2n} \right)^6 < \left( 1 + \left[ \sqrt{2n} \right] \right)^6 \leq (1+1)^6 = 2^6 \sqrt{2n};
\]

hence, for \( n > 500 \),

\[
8 \cdot (2n)^{3(\sqrt{2n}+1)} < 2^3 + 18 \cdot \sqrt{2n} + 18 \left( \frac{2n}{2^n} \right)^{2/3} < 4^{10} \left( \frac{2n}{2^n} \right)^{2/3} \leq 4^{2n};
\]
vii) for \( n > 500 \) this was proved in (vi); now each odd prime in the list 2, 3, 5, 7, 13, 23, 43, 83, 163, 317, 631 is less than twice the preceding prime in the list; if \( n \leq 500 \) there is a pair of consecutive terms \( p, q \) in this list for which \( p \leq n < q \); since \( q < 2p \leq 2n \) this means \( q \) is a prime strictly between \( n \) and \( 2n \);

viii) immediate from (vii).

13. i) \( (2n)^x < \prod_{n \leq p < 2n} p < (2n)^{\pi(2n) - \pi(n)} \)

and the desired conclusion follows;

ii) the equality follows by taking logs on both sides of the expression for \( (2n)^x \); the parenthetical expression is \( > 1 \) for the values of \( n \) specified;

iii) immediate from (i) and (ii) ;
\[ w) \quad (\pi(2n) - \pi(n)) \ln n < \sum_{p \leq 2n} \ln p = \ln P_n < (n-1) \ln 4 < \frac{7n}{5} \quad \text{for } n \geq 2, \]

where at the 2nd inequality we used \( \pi \geq 12 \) \( i) \);

\[ v) \quad \text{direct computation yields} \]
\[
\frac{n}{\text{ln}^2 n} < \begin{cases} 
2 & \frac{[6,8]}{[9,39]} \\
3 & \frac{[36,150]}{[135,500]} \\
9 & \frac{[321,1000]}{[720,2500]} \\
25 & \frac{50}{100}
\end{cases}
\]

\[ vi) \quad \text{for } n \geq 90, \quad \pi(2n) - \pi(n) > \frac{n}{3 \ln n} > 2; \quad \text{for} \]
\[ 6 \leq n < 90 \quad \text{one sees the truth of the assertion} \]
\[ \text{by checking the data given in the proof of } (v) ; \]

\[ vii) \quad \text{by } (vi), \quad \pi(2p_n) - \pi(p_n) \geq 2 \quad \text{for } p_n \geq 6; \quad \text{since} \]
\[ p_6 = 13 < 2 \cdot 7 = 2p_4 \quad \text{and} \quad p_7 = 17 < 2 \cdot 11 = 2p_5 \quad \text{the} \]
\[ \text{result is correct for } n \geq 4; \]
viii) by (vi), for \( n \geq 6 \) there are at least 2 primes between \( n \) and \( 2n \); at most one of these may be \( \geq 2n - 2 \); direct checking proves the result for \( n = 4 \) and \( n = 5 \);

ix) this follows from (v) and the fact that \( \frac{n}{\ln(n)} \) increases without bound as \( n \) increases.

14. i) This is true for \( n = 1, 2, 3, 4, 5 \) as can be seen by direct checking; suppose true for some \( k \), \( k \geq 6 \), then we have, using \( \# 13 (v) \),

\[
\Pi(2^{k+1}) < \Pi(2^k) + \frac{2^{k+1}}{5k \ln 2} < \frac{2^{k+1} + 17(k+1)}{20k} \leq \frac{2^{k+2}}{(k+1) \ln 2}
\]

where only at the last inequality do we need \( k \geq 6 \);

ii) let \( 2^{k-1} \leq n < 2^k \), so that

\[
\Pi(n) \leq \Pi(2^k) < \frac{2^{k+1}}{k \ln 2} < \frac{4 \cdot 2^{k-1}}{\ln 2} < 4 \cdot \frac{n}{\ln n} ;
\]
\[ \text{iii) using (\text{v}), } \pi(2n) > \pi(n) + \frac{n}{3 \ln 2n} > 1 + \frac{n}{3 \ln 2n}; \]

\[ \text{hence } \pi(n) \geq \pi(2 \left\lceil \frac{n}{2} \right\rceil) \geq 1 + \frac{[n/2]}{3 \ln 2 \left\lceil n/2 \right\rceil} \geq 1 + \frac{n/4}{3 \ln n} \]

\[ = 1 + \frac{n}{12 \ln n}; \]

\[ \text{\(\text{iv})\) this follows from (\text{iii}) and (\text{iii}) when } x \text{ is an integer } \geq 2; \text{ since } \frac{1}{12} (\frac{x}{\ln x} - \frac{[x]}{\ln [x]}) < 1 \text{ and } \frac{x}{\ln x} \text{ is increasing the result follows from (\text{iii}) and (\text{iii}) (with some special attention paid to } 2 < x < 3). \]

15. i) \[ \pi(mn) - \pi(m) > \frac{mn}{12 \ln mn} - \frac{4m}{\ln m} \]
\[ > \frac{192 m}{12 \ln m^2} - \frac{4m}{\ln m} = \frac{4m}{\ln m} \geq \frac{4n}{\ln n} > \pi(n); \]

\[ \text{ii) } \pi(mn) - \pi(m) \geq \pi(2m) - \pi(m) \]
\[ > \frac{m}{3 \ln 2m} \geq \frac{4000}{3 \ln 8000} > 148 > \frac{4n}{\ln n}. \]

16. i) \[ \pi(p_m p_n) > \pi(p_m) + \pi(p_n) \]
\[ = m + n = \pi(p_{m+n}); \]
(ii) this is true by (i) for $2 \leq n \leq m$, $4 \leq m$; thus we need only check the cases where $n = 1, 2, 3$ and $n \leq m$; but, by #13 (vii),

$$p_1, p_m > 2p_m > p_{m+2},$$

$$p_2, p_m > p_m + 2p_m > p_m + p_{m+1} > p_m + 2p_m$$

$$p_3, p_m > p_{m-1} + 4p_m > p_{m+1} + 3p_m > p_{m+2} + 2p_m > p_{m+3} + p_{m+1}$$

(iii) immediate from (ii);

(iv) multiply the inequalities in (iii).

17. i) $\prod_{d \mid n} \prod_{k=1}^{d} \frac{x - e^{\frac{2\pi ikd}{n}}}{x - e^{\frac{2\pi ik}{n}}} = \prod_{d \mid n} \prod_{k=1}^{n/d} \frac{x - e^{\frac{2\pi ikd}{n}}}{x - e^{\frac{2\pi ik}{n}}} = \prod_{d \mid n} \prod_{k=1}^{n/d} (x - e^{\frac{2\pi ikd}{n}}) = \prod_{t=0}^{n-1} (x - e^{\frac{2\pi it}{n}}) = x^n - 1$.

(ii) $F_1(x) = x - 1$ and the proposition is true; assume the proposition is true for all positive integers $< n$; then $\prod_{d \mid n} F_d(x)$ is monic.
and integral and, therefore, so also is $F_n(x)$ since $x^n - 1 = F_n(x) \prod_{d \mid n} F_d(x)$; noting that there are exactly $\varphi(n)$ values of $k$ for which $(k, n) = 1$ we see the degree of $F_n(x)$ is $\varphi(n)$.

(iii) true for $n = 2$ and the identity

$$x^n - 1 = F_n(x) \prod_{d \mid n} F_d(x)$$

shows the proposition carries over to $n$ from integers $< n$ (note that $F_1(0) = -1$ and $x^n - 1$ is also $-1$ at $x = 0$);

(iv) if $p | F_n(a)$ then $p | a^n - 1$, which implies $(a, p) = 1$;

(v-a) suppose $n = qt + r$, $0 \leq r < t$; then

$$1 \equiv a^n = (a^t)^q a^r \equiv a^r \pmod{p};$$

thus $r = 0$ (by definition of $t$) and $t | n$. 

6) let $c$ be either $p$ or $a+p$; then $p$ divides each of $c^t-1$ and $F_n(c)$; but since $c^t-1 = \prod_{\text{all } d|c} F_d(c)$ and $t|n$, $t<n$, we know $(c^t-1)F_n(c)$, and therefore also $p^2$, divides $c^n-1 = \prod_{d|n} F_d(c)$; hence $c^t-1 \equiv 0 \pmod{p^2}$;

c) from (b),

$$(a+p)^n-1 = a^n-1 + \sum_{j=0}^{n-1} \binom{n}{j} a^j p^{n-j} \equiv n a^{n-1} p \pmod{p^2};$$

but $(a,p)=1$ so $p|n$;

d) if $p|n$ then, by (a) and (c), $t=n$; but $a^{p-1} \equiv 1 \pmod{p}$ and, since $t$ is the smallest number with $a^t \equiv 1 \pmod{p}$ we must have $t|p-1$;

since $t=n$, $n|p-1$;

vi) that $F_n(ny_1p_1\ldots p_k) > 1$ for $y$ sufficiently large follows from the fact that the leading coefficient of $F_n(x)$ is 1; since

$$ny_1p_1\ldots p_k \equiv 0 \pmod{np_1\ldots p_k}$$

it is clear that $F_n(ny_1p_1\ldots p_k) \equiv F_n(0) \pmod{np_1\ldots p_k}$;
the last congruence follows from (ii); finally, let \( p \) be any prime divisor of \( F_n(\cdot p \cdot \cdot \cdot p) \); then \( p \neq p_j \) for \( 1 \leq j \leq k \) and also \( p \nmid n \); therefore, by (v-\( \alpha \)), \( p \equiv 1 \pmod{n} \);

\( \text{vii)} \) by (vi) no finite collection \( p_1, \ldots, p_k \) can exhaust all primes \( p \) with \( p \equiv 1 \pmod{n} \); the conclusion follows.

18. i) \( (e_m)^{\frac{n}{\alpha}} = e^{\frac{2\pi i m}{n} \cdot \frac{n}{\alpha}} = e^{\frac{2\pi i m}{\alpha}} \equiv 1 \) precisely when \( \alpha \mid m \); since the derivative of \( x^{\frac{n}{\alpha}} - 1 \) is \( \frac{n}{\alpha} x^{\frac{n}{\alpha} - 1} \) we see no zero of \( x^{\frac{n}{\alpha}} - 1 \) is of order \( > 1 \);

\( \text{ii)} \) the number of elements in \( A_j \) which divide \( d \) is just \( (\frac{s}{j}) \); consequently the power of \( x - e_m \) in \( g(x) \) is just \( (\frac{s}{1}) + (\frac{s}{3}) + (\frac{s}{5}) + \cdots \); note that \( x - e_m \) is not a factor of \( F_n(x) \) since \( d > 1 \); similar reasoning applies to \( f(x) \);
iii) when \( d = 1 \), \( x - e_m \) appears exactly once in each of \( F_n(x) \), \( x^n - 1 \) and in no other factors of \( q \) and \( f \); thus, since \( q \) and \( f \) are monic and have the same zeros to the same orders, and since \( \binom{5}{1} + \binom{5}{3} + \binom{5}{5} + \cdots = 1 + \binom{5}{2} + \binom{5}{4} + \cdots \) we conclude \( f \) and \( q \) are identical; the result follows;

iv) the \( A_j \) corresponding to \( np \) are the same as for \( n \); thus, since \( x^{\frac{np}{\alpha}} = (x^p)^{n/\alpha} \), the conclusion follows;

v) let \( A_j \), \( 1 \leq j \leq r+1 \), be the sets corresponding to the \( A_j \) for \( n \); then \( F_{np}(x) \) \( F_n(x) = \)

\[
\frac{(x^{np} - 1)}{\prod_{j \in \text{odd}}^{s \leq j \leq r+1} \prod_{\alpha \in A_j} (x^{\frac{np}{\alpha}} - 1)} \cdot \frac{(x^n - 1)}{\prod_{j \in \text{odd}}^{s \leq j \leq r} \prod_{\alpha \in A_j} (x^{\frac{n}{\alpha}} - 1)}; \\
\frac{(x^{np} - 1)}{\prod_{j \in \text{even}}^{s \leq j \leq r+1} \prod_{\alpha \in A_j} (x^{\frac{np}{\alpha}} - 1)} \cdot \frac{(x^n - 1)}{\prod_{j \in \text{even}}^{s \leq j \leq r} \prod_{\alpha \in A_j} (x^{\frac{n}{\alpha}} - 1)};
\]

for each \( \alpha \) containing the factor \( p \) the factor \( x^{np} - 1 \) in the expression for \( F_{np}(x) \) is canceled by the factor \( x^{np} - 1 \) in the expression for \( F_n(x) \); consequently the right side is just \( F_n(x^p) \);
vi) from (v), \( F_p(x^p) = \frac{F_1(x^p)}{F_1(x)} = \frac{x^{p-1}}{x-1} = x^{p-1} + \cdots + 1;\)

vii) \( F_1(1) = x-1 \) so \( F_1(1) = 0; \) by (vi), \( F_{np}(1) = F_n(1); \)

thus \( F_{p^a}(1) = F_{p^{a-1}}(1) = \cdots = F_p(1), \) and this last quantity is \( p; \) by (vi); if \( n \) has 2 distinct prime factors, say \( n = mq^a \) where \( m > 1, \) \( (m, q) = 1, \)

\( q \) prime then, using (vi) and (v),

\( F_n(1) = F_{mq^{a-1}}(1) = F_{mq^{a-2}}(1) = \cdots = F_{mq}(1) = \frac{F_m(1)}{F_m(1)} = 1;\)

viii) this follows immediately from (vii); when \( d \) contains a square we do not find \( x_\sqrt{d}-1 \) in either numerator or denominator; when \( d = 1 \)

we get the factor \( x^n-1 \) and when \( d \) is the product of \( j \) distinct primes then \( x_\sqrt{d}-1 \) is in the numerator when \( j \) is even and in the denominator when \( j \) is odd;

ix) using (viii), we see that when \( d = \frac{n}{P_i}, \)

\( \mu(d) = 1 \) so \( x^{P_i}-1 \) is a factor of \( F_n(x); \)
all other factors than those of this form are congruent to $-1 \pmod{x^{p_{t+1}}}$ since all exponents of $x$ in these factors exceed $p_{t+1}$ as a consequence of $p_1 + p_2 > p_t$; the 2nd congruence follows for similar reasons.

i) for each $i$, $1 \leq i \leq t-1$, there is a $j$, $0 \leq j \leq p_t - 1$ for which $x^{p_i} x^j = x^{p_t}$; since there are $t-1$ such $i$ the result follows.

19. i) This is by direct examination;

ii) for $n = 7$, each of 12, 13, ..., 29 are in $S_6$ (and in $S_7$) so each of $12 + p_7, 13 + p_7, \ldots, 29 + p_7$ are in $S_7$; if 12, 13, ..., 29 + $p_7 + \cdots + p_{n-1}$ are in $S_{n-1}$ (and $S_n$) then 12 + $p_n, 13 + p_n, \ldots, 29 + p_7 + \cdots + p_n$ are in $S_n$; these blocks overlap since (using $\ast 12 \nu i$) $12 + p_k < 29 + p_7 + \cdots + p_{k-1}$ for $k \geq 8$;
iii) immediate from (ii) ;

iv) direct inspection and (iii) ;

v) direct inspection and (iv) .

20. i) \( \emptyset, S \), and unions of open sets are clearly open; if \( \emptyset_i, \ldots, \emptyset_t \) are open and \( x \in \emptyset_i \cap \cdots \cap \emptyset_t \) then there are integers \( s_1, \ldots, s_t \) such that \( x + ns_i \in \emptyset_i \) for all integers \( n \); thus \( x + ns_1, \ldots, s_t \in \emptyset_i \) for all \( i, 1 \leq i \leq t \), and all integers \( n \); i.e. \( x \) is in an arithmetic progression contained in \( \emptyset_i \cap \cdots \cap \emptyset_t \) and, therefore, this intersection is open ;

ii) the complement of an arithmetic progression with difference \( d \) is a union of \( d-1 \) arithmetic progressions with difference \( d \); since both sets are open and they mutually exhaust \( S \) they must both be closed ;
iii) Immediate from (ii);

iv) this is true since each integer other than ±1 has a prime factor;

v) if there were only finitely many primes the set A of (iv) would be closed and consequently would have an open complement; since the complement \{-1, 1\} is not open we conclude there are infinitely many primes.

21. When \( n \) is an odd prime Wilson's theorem tells us \((n-2)! \equiv -(n-1)! \equiv 1 \pmod{n}\) so

\[
\left[ \frac{(n-2)!}{n} \right] = \frac{(n-2)!}{n} - 1
\]

is an odd integer; when \( n \) is composite IX \#11 tells us \[
\left[ \frac{(n-2)!}{n} \right] = \frac{(n-2)!}{n}
\]

is an even integer; therefore when either \( n \) or \( n+2 \) is composite the term of the summand corresponding to \( n \) will be 0 since the sine of an even
multiple of $\frac{n}{2}$ is 0, while if $n$ and $n+2$ are each prime then the term is the product of the sine of an odd multiple of $\frac{n}{2}$ with another sine of an odd multiple of $\frac{n}{2}$, hence is $(−1)(−1)=1$; the 2 accounts for 3,6 and 5,7.

22. i) Immediate;

\[\sum_{k=1}^{m} F(k) = 1 + \pi(m) \text{ by (i)}; \text{ now if } m < p_n \text{ then } 1 + \pi(m) \leq n, \text{ while if } m \geq p_n \text{ then } 1 + \pi(m) \geq n; \text{ since } p_n < 2^{2^n}, \text{ by (iv) (iv)}, \text{ the sum } \sum_{m=1}^{2^n} \left[ \frac{n}{1 + \pi(m)} \right] \text{ counts } 1 \text{ for each } m < p_n; \text{ thus this sum plus } 1 \text{ is exactly } p_n.\]
Quaternions, Complex Numbers, e-Sums of 4 and 2 Squares - Solutions

1. i) The determinant of \((-\frac{a}{b} \quad \frac{b}{a})\) is \(|a|^2 + |b|^2\) and this is 0 if and only if \(a = b = 0\); the upper left elements in the two products of \((\frac{1}{i}, \frac{1+i}{i})\) and \((\frac{i}{-1}, \frac{i}{-1})\) are -1 and 2i-1 so \(C\) is non-commutative; for \(a, b\) real \((-\frac{a}{b} \quad \frac{b}{a}) = (-\frac{b}{a} \quad \frac{a}{b})\); all else is routine verification;

ii) the correspondence is \((-\frac{a}{b} \quad \frac{b}{a}) \leftrightarrow a + i b\);

iii) If \(a' = a + i b, b' = c + i d\), where \(a, b, c, d\) are in \(\mathbb{R}\), then \((-\frac{a'}{b'} \quad \frac{b'}{a'}) = a (\frac{1}{0} \quad \frac{0}{1}) + b (\frac{1}{i} \quad \frac{i}{0}) + c (\frac{0}{0} \quad \frac{1}{0}) + d (\frac{0}{1} \quad \frac{-i}{0})

\[
\begin{pmatrix}
\begin{array}{cccc}
 a & -b & -c & -d \\
 b & a & -d & c \\
 c & d & a & -b \\
 d & -c & b & a \\
\end{array}
\end{pmatrix} =
\begin{pmatrix}
\begin{array}{cccc}
 1 & 0 & 0 & 0 \\
 0 & 1 & 0 & 0 \\
 0 & 0 & 0 & 1 \\
 0 & 0 & 0 & 0 \\
\end{array}
\end{pmatrix}
\begin{pmatrix}
\begin{array}{cccc}
 0 & -1 & 0 & 0 \\
 1 & 0 & 0 & 1 \\
 0 & 0 & -1 & 0 \\
 0 & 0 & 1 & 0 \\
\end{array}
\end{pmatrix} + \begin{pmatrix}
\begin{array}{cccc}
 0 & 0 & -1 & 0 \\
 0 & 0 & 1 & 0 \\
 0 & 1 & 0 & 0 \\
 1 & 0 & 0 & 0 \\
\end{array}
\end{pmatrix} + \begin{pmatrix}
\begin{array}{cccc}
 0 & 0 & -1 & 0 \\
 0 & 0 & 1 & 0 \\
 0 & 1 & 0 & 0 \\
 1 & 0 & 0 & 0 \\
\end{array}
\end{pmatrix} + \begin{pmatrix}
\begin{array}{cccc}
 0 & 0 & -1 & 0 \\
 0 & 0 & 1 & 0 \\
 0 & 1 & 0 & 0 \\
 1 & 0 & 0 & 0 \\
\end{array}
\end{pmatrix};
make the correspondence

\[
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \leftrightarrow \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} \leftrightarrow \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix},
\]

\[
\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \leftrightarrow \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \leftrightarrow \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix};
\]

the assertion is now a matter of routine verification;

\(\text{i)}\) one needs only show the \(4 \times 4\) matrices of \(R^2\) which are displayed in the proof of (iii) are independent and this is clear;

\(\text{v)}\) that this set is a subfield is clear and the non-commutativity is proved by the example given in the proof of (i);

\(\text{vi)}\) this follows from associativity and distributivity properties of addition and multiplication.
2. i) \( \alpha - \overline{\alpha} = 2 \left( ib + jc + kd \right) = 0 \) if and only if \( b = c = d = 0 \) since \( i, j, k \) are independent;

\[ N\alpha = a^2 + b^2 + c^2 + d^2 \]
\[ = a^2 + (-b)^2 + (-c)^2 + (-d)^2 = N\overline{\alpha} \]
\[ T\alpha = 2a = (a + ib + jc + kd) \]
\[ + (a - ib - jc - kd) = \alpha + \overline{\alpha} \]

ii) \( N\alpha = a^2 + b^2 + c^2 + d^2 = 0 \) if and only if \( a = b = c = d = 0 \); i.e. if and only if \( \alpha = 0 \);

iv) direct verification;

v) \[ \overline{\alpha} \cdot 1 = \overline{\alpha} = \overline{1} \cdot \overline{\alpha} , \]
\[ \overline{\alpha} i = \overline{ia - b - kc + jd} = -b - ia - jd + kc = \]
\[ (-i)(a - ib - jc - kd) = i \overline{\alpha} \); similarly \( \overline{\alpha} j = j \overline{\alpha} , \]
\[ \overline{\alpha} k = k \overline{\alpha} \); now use (iv) and distributivity to obtain \( \overline{\alpha} \beta = \overline{\beta} \overline{\alpha} \);

vi) clear;
vii) \( N(\alpha \beta) = (\alpha \beta)(\overline{\alpha \beta}) = (\alpha \beta)(\overline{\beta} \overline{\alpha}) = \alpha(N\beta)\overline{\alpha} = (\alpha \overline{\alpha})(N\beta) = (N\alpha)(N\beta) \);

viii) substitution yields the result immediately.

3. i) Let \( f(\alpha) = 0 \), where \( f \) is a monic integral polynomial; since \( \alpha \) also satisfies the principal equation there is a monic integral irreducible polynomial \( g \), of degree 1 or 2, satisfying \( g(\alpha) = 0 \); if \( \alpha \) is not rational then \( g(x) = 0 \) is the principal equation, while if \( \alpha \) is rational \( g^2(x) = 0 \) is the principal equation; in either case \( T\alpha \) and \( N\alpha \) are integers; the reverse direction is clear by \#2(viii);

\[ w) \text{ clearly } \mathbb{L} \subseteq \mathbb{H} \text{ and } \rho \in \mathbb{H} \setminus \mathbb{L}; \text{ if } \beta = \rho + \alpha, \alpha = a + ib + jc + kd \in \mathbb{L} \text{ then } \]
\[ T\beta = \rho + \alpha + \overline{\rho} + \overline{\alpha} = 1 + \alpha + \overline{\alpha} \]
\[ = 1 + T\alpha = 1 + 2a \in \mathbb{Z}, \]
\[ N \beta = (\rho + \alpha)(\bar{\rho} + \bar{\alpha}) = \rho \bar{\rho} + \alpha \bar{\rho} + \bar{\alpha} \rho + \alpha \bar{\alpha} = (\frac{1}{4} + \frac{1}{4} + \frac{1}{4} + \frac{1}{4}) + (a - b - c - d) + (a^2 + b^2 + c^2 + d^2) \in \mathbb{Z} \]

so, by (i), \( \mathcal{H} \subset \mathbb{I} \); now \( \frac{3}{5}i + \frac{4}{5}j \) is not in \( \mathcal{H} \) but \( T(\frac{3}{5}i + \frac{4}{5}j) = 0 \in \mathbb{Z} \), \( N(\frac{3}{5}i + \frac{4}{5}j) = \frac{9}{25} + \frac{16}{25} = 1 \in \mathbb{Z} \)

so \( \frac{3}{5}i + \frac{4}{5}j \in \mathcal{I} \);

\( \text{iii) when } A = \mathcal{L} \text{ this is obvious}; \text{ when } \)

\( A = \mathcal{H} \text{ note first that } \bar{\rho} = \rho + (-i - j - k) \in \mathcal{H} \)

so if \( \alpha = \rho + \beta \in \mathcal{H}, \beta \in \mathcal{L}, \) then \( \bar{\alpha} = \bar{\rho} + \overline{\beta} \in \mathcal{H} \);

further, \( i(\rho + \beta) = \rho + (-1 - j + i\beta) \) so when \( \rho + \beta \in \mathcal{H}, \beta \in \mathcal{L}, \) so also is \( i(\rho + \beta) \in \mathcal{H} \); similar arguments work for \( j\alpha \) and \( k\alpha \);

\( \text{iv) put } \alpha = \frac{3}{5}i + \frac{4}{5}j; \text{ by the proof of (iii)} \)

we know \( \alpha \in \mathcal{I} \); now \( i\alpha = -\frac{3}{5} + \frac{4}{5}k \) and \( T(i\alpha) = -\frac{6}{5} \notin \mathbb{Z} \); thus by (i) \( i\alpha \notin \mathcal{I} \);

\( \text{v) as we have seen in (iv) } \mathcal{I} \text{ is not closed under multiplication and is, therefore, not} \)
an integral domain; using (iii) it is routine verification to prove \( \mathcal{L} \) and \( \mathcal{H} \) are integral domains;

vi) if \( \alpha = a + ib + jc + kd \) is in an integral domain of \( \mathcal{I} \) which contains \( \mathcal{H} \) then since \( \alpha \), 
- \( i\alpha \), -\( j\alpha \), -\( k\alpha \) are all in \( \mathcal{I} \), we know 
\[ T\alpha = 2a \in \mathbb{Z}, \quad T(-i\alpha) = 2b \in \mathbb{Z}, \quad T(-j\alpha) = 2c \in \mathbb{Z}, \]
\[ T(-k\alpha) = 2d \in \mathbb{Z}; \] further \( N\alpha = a^2 + b^2 + c^2 + d^2 \in \mathbb{Z} \);
if any one of \( a, b, c, d \) is half an odd integer this last fact implies they are all halves of odd integers; since \( a, b, c, d \) are all integers or all halves of odd integers we see \( \alpha \in \mathcal{H} \);
this shows \( \mathcal{H} \) is maximal in \( \mathcal{I} \);

vii) \( \alpha p + ib + jc + kd \) is in \( \mathcal{L} \) and hence in \( \mathcal{H} \) when \( a \) is even; when \( a \) is odd this equals \( \alpha + \beta \), where \( \beta = (a-1)\alpha + ib + jc + kd \in \mathcal{L} \); on the other hand \( \alpha + \alpha = (1 + 2a)\alpha + i(6-a) + j(c-a) + k(d-a) \).
4. i) Each element of \( \mathcal{L} \) is its own left associate; if \( \alpha \in \mathbb{H} \setminus \mathcal{L} \) we may write
\[
\alpha = 2(a + bi + jc + kd) + \alpha_1,
\]
where
\[
\alpha_1 = \frac{1}{2}(e + if + jg + kh);
\]
e, f, g, h are all \( \pm 1 \), a, b, c, d are in \( \mathbb{Z} \); since \( N\alpha_1 = 1 \), \( \alpha \alpha_1 \) is a left associate of \( \alpha \); finally
\[
\alpha \alpha_1 = (a + ib + jc + kd)(e - if - jg - kh) + 1 \in \mathcal{L};
\]

ii) let \( \alpha = a \rho + ib + jc + kd \) and try for
\[
\beta = e \rho + if + jg +kh; \quad \text{then } \alpha - m \beta = \frac{a - me}{2} + i \frac{a - me + 2b - 2mf}{2} + j \frac{a - me + 2c - 2mg}{2} + k \frac{a - me + 2d - 2mh}{2},
\]
now choose \( e, f, g, h \) so that each of the following four quantities falls between \( -\frac{m}{2} \) and \( \frac{m}{2} \) inclusive: \( a - me, \frac{a - me + 2b}{2} - mf \), \( \frac{a - me + 2c}{2} - mg \), \( \frac{a - me + 2d}{2} - mh \); with these choices, \( N(\alpha - m \beta) \leq \frac{m^2}{16} + \frac{3m^2}{4} < m^2 \);

iii) let \( m = \beta \bar{\beta} \) and choose \( \delta_1 \) so that
\[
N(\beta \alpha - m \delta_1) < m^2; \quad \text{put } \delta_1 = \alpha - \beta \delta_1;
then \( \alpha = \beta \delta_1 + \delta_1 \) and \( mN\delta_1 = N (\beta \delta_1) = N(\beta \alpha - m\delta_1) < m^2 \); consequently \( N\delta_1 < m = N\beta \);

the other part goes the same way;

iv) under the hypothesis each of \( \delta, \delta_1 \) is a left divisor of the other; thus \( \delta = \delta_1 \delta', \delta_1 = \delta \delta'' = \delta_1 \delta' \delta'' \) and \( \delta' \delta'' = 1 \); this means \( \delta \) and \( \delta_1 \) are left associates; on the other hand if \( \delta \) is a left \( \text{gcd} \) of \( \alpha \) and \( \beta \) and \( \delta_1 = \delta \eta \) then from \( \delta = \delta_1 \delta_1 \), we find \( \delta = \delta_1 N^{-1} \delta_1 \); thus \( \delta_1 \)

left divides all numbers left divisible by \( \delta \), so \( \delta_1 \) is a left \( \text{gcd} \) of \( \alpha \) and \( \beta \);

v) let \( \delta \) be an element of minimal positive

norm in \( A \); further, let \( \delta_1 \) be a common

left divisor of \( \alpha \) and \( \beta \); then, by (iii),

\[
\alpha = \delta \alpha_1 + \alpha_2, \quad N\alpha_2 < N\delta;
\]

\[
\beta = \delta \beta_1 + \beta_2, \quad N\beta_2 < N\delta;
\]

\[
\delta_1 = \delta \delta' + \delta'', \quad N\delta'' < N\delta;
\]
since $\alpha - \delta \alpha_1$, $\beta - \delta \beta_1$ are in $A$ we must have $N\alpha_2 = N\beta_2 = 0$ so $\alpha_2 = \beta_2 = 0$ and $\delta$ is a common left divisor of $\alpha$ and $\beta$; also since $\delta_1$ is a left divisor of $\alpha$ we know $\alpha$ is a left divisor of $\delta_1$ so $\delta_1 - \delta \delta'$ is in $A$ which implies $\delta'' = 0$ and, therefore, $\delta$ is a left divisor of $\delta_1$;

vi) if $\alpha = a + ib + jc + kd$ and $N\alpha = 1$ then $a^2 + b^2 + c^2 + d^2 = 1$; since $a, b, c, d$ are either all integers or all halves of odd integers the units are precisely those quaternions corresponding to $(a, b, c, d)$ one of: $(\pm 1, 0, 0, 0), (0, \pm 1, 0, 0), (0, 0, \pm 1, 0), (0, 0, 0, \pm 1), (\pm \frac{1}{2}, \pm \frac{1}{2}, \pm \frac{1}{2}, \pm \frac{1}{2})$, and there are just 24 of these; that every unit is a two-sided divisor of each element of $H$ follows from (iii) and the fact that no element of $H$ has positive norm smaller than 1; as for the
units in \( \mathcal{L} \), this is clear since \( a^2 + b^2 + c^2 + d^2 = 1 \) for integers \( a, b, c, d \) only if one of these is \( \pm 1 \) and all the others are \( 0 \);

\[ \text{w) if } (\alpha, n) = \alpha \nu + n \bar{\nu} \text{ were a unit then } \]
\[ 1 = (\alpha \nu + n \bar{\nu})(\overline{\alpha \nu + n \bar{\nu}}) = (\alpha \nu + n \bar{\nu})(\overline{\nu \alpha + \bar{\nu} n}) \]
\[ \equiv 0 \pmod{n}, \text{ contrary to fact.} \]

5. i) If \( \alpha \) is a prime and \( \beta = \nu \alpha \nu \), where \( \nu \) and \( \nu \) are units then \( N\beta = N\alpha > 1 \) so \( \beta \) is not a unit; if \( \beta = \delta \gamma, N\gamma > 1, N\delta > 1 \) then \( \alpha = (N^{-1}\gamma)(\delta \nu^{-1}), N(N^{-1}\gamma) = N\gamma > 1, N(\delta \nu^{-1}) = N\delta > 1 \) and \( \alpha \) would not be prime; thus \( \beta \) is prime;

\[ \text{w) if } \alpha \text{ is not a prime in } \mathcal{H}, \alpha = \beta \delta, \]
\[ N\beta > 1, N\delta > 1; \text{ but then } N\alpha = N\beta N\delta \text{ is not a rational prime;} \]
iii) let $\Pi = (\alpha, p)$, $\alpha = \Pi \alpha_1$, $p = \Pi p_1$; by

$\#4(\text{vi})$, $N\Pi > 1$ so, from $p^2 = Np = N\Pi Np_1$, 
either N\Pi = p$ or $N\Pi = p^2$; in the 1st case we
are done; in the other case $Np_1 = 1$ and,
therefore, $\alpha = \Pi \alpha_1 = p \overline{p}_1 \alpha_1$ which means $\alpha$
is divisible by $p$; this contradicts the hypoth-
esis that $\alpha$ is primitive;

iv) for $p$ an odd rational prime there
are rational integers $m$ and $n$ for which
$1 + m^2 + n^2$ is divisible by $p$ (see e.g. XI*14(ii));
let $\alpha = 1 + im + jn$; then $(p, \alpha)$ is prime
and $N((p, \alpha)) = p$; also $2 = (1 + i)(1 - i)$;

v) in view of (ii) we need only prove one
direction; let $\alpha$ be a prime in $\mathcal{H}$ and sup-
pose $p$ is a rational prime dividing $N\alpha$;
then if $\mathfrak{D} = (\alpha, p)$ we must have $\alpha = \mathfrak{D}\alpha_1$, and
by (iii), \( N \sigma = p \); since \( \alpha \) is prime in \( \mathfrak{H} \) this means \( N \alpha \equiv 1 \) so \( N \alpha = N \sigma = p \);

vi) since \( 2 \mid N \alpha \), \( \alpha = a + ib + jc + kd \in \mathbb{L} \) and \( a + b + c + d \equiv N \alpha \equiv 0 \pmod{2} \);
now put \( \beta = \frac{1}{2}((a + b) + i(b - a) + j(c + d) + k(d - a)) \)
and observe that \( \alpha = (1 + i) \beta \);

vii) by (vi), \( \alpha = (1 + i)^{\tau} \delta \), where \( N \delta \) is odd;
\( (1 + i)^2 = 2i \) so \( (1 + i)^{s} = (1 + i)^{\tau} n \), where \( n \) is a rational integer, \( n \) is a unit, and \( \tau = 0 \) or \( 1 \);
now \( \delta = t \sigma \), where \( t \in \mathbb{Z} \) and \( \sigma \) is primitive;
thus \( \alpha = (1 + i)^{\tau} m \rho \sigma = (1 + i)^{\tau} m \beta \rho \), where \( N \sigma = \beta \rho \) and \( N \beta = N \sigma = N \delta \) is odd; if \( \beta \) is not in \( \mathbb{L} \), by #4(i) we can make it be in \( \mathbb{L} \)
by altering the unit \( \rho \);

viii) by (iii) if \( \pi_1 = (\sigma, p_1) \) then \( N \pi_1 = p_1 \);
putting \( \sigma = \pi_1 \delta_2 \) we see that \( p_2 \) divides \( N \delta_2 \).
so, again by (iii), if \( \Pi_2 = (\delta_2, p_2) \) then \( \mathcal{N}\Pi_2 = p_2 \); repeating yields \( \delta = \Pi_1 \cdots \Pi_5 \); now, by (vii), 
\( \alpha = (1 + i)^7 \beta \mathcal{N} \) for some primitive \( \beta \) of odd norm in \( \mathcal{L} \) and \( \mathcal{N} \) some unit; by the 1st part (with \( \delta = \beta \)) we see \( \alpha = (1 + i)^7 \Pi_1 \cdots \Pi_5 \) (\( \Pi_5 \) is the earlier \( \Pi_5 \) multiplied on the right by \( \mathcal{N} \));

ix) let \( \beta = \tau_1 \cdots \tau_5 \); then \( \mathcal{N}\beta = p_1 \cdots p_5 \) and 
\( \Pi_1 = (\beta, p_1) \); since \( \tau_1 \) divides each of \( \beta \) and \( p_1 \) 
so \( \tau_1 \) divides \( \Pi_1 \); since \( \tau_1 \) and \( p_1 \) are primes they must be associates; repeat with

\( \beta_2 = \tau_2 \cdots \tau_5 \), \( \mathcal{N}\beta_2 = p_2 \cdots p_5 \), etc.;

x) immediate from (vii) - (ix);

xi) \( 7 = (1 + i + j + 2k)(1 - i - j - 2k) \)
\[= (1 - i - j + 2k)(1 + i + j - 2k) \].
6. i) All quaternions of the form \((1+i)\mathcal{N}\), where \(\mathcal{N}\) is a unit have norm 2 and, by #4(vi), there are 24 of them; on the other hand all quaternions of norm 2 are in \(\mathbb{L}\) and \(a^2+b^2+c^2+d^2 = 2\) implies precisely 2 of the \(a, b, c, d\) are \(\pm 1\); the number of such quaternions in \(\mathbb{L}\) is \(4 \binom{4}{2} = 24\);

ii-a) for each quadruple \(A, B, C, D\) satisfying (1) there is exactly one quadruple \(A_1, B_1, C_1, D_1\) satisfying (2), namely, let \(A_1 = A, D_1 = D\) and \(B_1, C_1\) be chosen so that 
\[-aA + B_1 \equiv B, -bA + C_1 \equiv C \pmod{p}\];
the reverse direction is clear;

b) we may choose \(a, b\) so that \(a^2 + b^2 + 1\) is divisible by \(p\) (see XI #14(i)); then using (2) we have \(B^2 + C^2 + D^2 \equiv 2A(aB + bC) - (1 + a^2 + b^2)A^2 \equiv 2A(aB + bC) \pmod{p}\);
c) from (3) we see, when \( B \equiv C \pmod{p} \), that \( D \equiv 0 \pmod{p} \); hence the \( p \) solutions are obtained from \( A \), since all \( p \) possible values of \( A \) will be suitable; when \( B \not\equiv C \pmod{p} \) and \( a, b \) are as in (6) it is clear that 
\[
(B, C, p) = (a, b, p) = 1; \quad \text{thus, without loss of generality,} \quad (B, p) = (b, p) = 1; \quad \text{then there is a unique} \ E \ \text{such that} \ B \equiv bE \pmod{p} \ \text{and, for this} \ E, \ \text{we have} \ C \equiv -aE \pmod{p}; \quad \text{hence} \ O \equiv B^2 + C^2 + D^2 \equiv (b^2 + a^2)E^2 + D^2 \equiv -E^2 + D^2 \pmod{p}; \quad \text{therefore} \ D \equiv \pm E \pmod{p}; \quad \text{with} \ A \ \text{arbitrary,} \ E \ \text{any non-zero value (} B \not\equiv C \pmod{p} \) \ \text{and} \ D \equiv \pm E \pmod{p}, \ \text{we find altogether} \ 2p(p-1) \ \text{solutions};
\]

\[d) \] as in the proof of (c) we note that 
\[(a, b, p) = 1 \] so that we may assume without loss of generality that \( (b, p) = 1; \ \text{thus for each of the} \ p \ \text{possible values of} \ B \ \text{there are} \]
\( p - 1 \) values for \( C \) such that \( AB + 6C \equiv 0 \pmod{p} \); for each of these \( p^2 - p \) choices for \( B, C \) and every one of the \( p \) possible choices for \( D \) there is a unique \( A \); consequently there are exactly \( p(p^2 - p) \) quadruples \( A, B, C, D \) satisfying (3);

\[ e) \text{ by (c) and (d) the number of solutions is } p + 2p(p-1) + p(p^2 - p) = (p^2 - 1)(p + 1) + 1. \]

\[ \text{iii-a) If the assertion were false then } p \text{ would divide each of } a_0^2 + a_1^2, a_0^2 + a_2^2, a_0^2 + a_3^2 \text{ and then, since it also divides } N\alpha = a_0^2 + a_1^2 + a_2^2 + a_3^2, \text{ it would divide } 2a_0^2; \text{ thus } p \text{ would divide } a_0 \text{ and, thence, also } a_1, a_2, a_3 \text{ so would divide } \alpha, \text{ contrary to supposition;} \]

\[ 6.1) \beta + \delta i_{v+1} = a_0 + a_v^{-1} + a_{v+1} i_{v+1} + a_{v+2} i_v i_{v+1} = a_0 + a_v^{-1} + a_{v+1} i_{v+1} + a_{v+2} i_v i_{v+2} = \alpha; \]
similarly the expression for $x$ is correct;

2) this is clear since $i_v$ commutes with itself and with scalars;

3) for $a, b$ scalars $(a + bi_v)i_{v+1} = a i_{v+1} + bi_v i_{v+1} = ai_{v+1} - bi_{v+1} i_v = i_{v+1}(a - bi_v)$;

c) let $v$ be as in (a);

$$\alpha x = (\beta \eta - \delta \bar{\delta}) + (\beta \delta + \delta \bar{\eta})i_{v+1};$$

since $\beta \eta - \delta \bar{\delta}$ is of the form $a + bi_v$, and $(\beta \delta + \delta \bar{\eta})i_{v+1}$ is of the form $c i_{v+1} + d i_{v+2}$, with $a, b, c, d$ scalars, we see that when $p$ divides $\alpha x$ it must also divide each of $\beta \eta - \delta \bar{\delta}$ and $\beta \delta + \delta \bar{\eta}$; on the other hand if $p$ divides $\beta \eta - \delta \bar{\delta}$ then $\beta \eta \equiv \delta \bar{\delta}$ (mod $p$) so, multiplying by $\bar{\delta} \bar{\delta}$ yields $\beta \delta \bar{\eta} \bar{\delta} \equiv \delta \bar{\delta} \bar{\delta} \bar{\delta}$ (mod $p$); but since $\beta \bar{\delta} \equiv 0$ (mod $p$) (since $p$ does not divide $a_0^2 + a_v^2$) and $\beta \bar{\delta} \equiv - \delta \bar{\delta}$ (mod $p$) (since $p$ does divide $N\alpha$) we see $\eta \delta \equiv - \delta \bar{\delta}$ (mod $p$) and, therefore,
\[ \beta \bar{\eta} \equiv -\bar{x} \bar{\eta} \pmod{p} ; \text{ hence if } p \text{ divides } \beta \eta - \bar{x} \bar{\eta} \text{ it also divides } \beta \bar{x} + \bar{x} \bar{\eta} , \text{ and, therefore, divides } \alpha x ; \]

d) by (c), \( \alpha x \equiv 0 \pmod{p} \) is equivalent to \( \beta \eta \equiv x \bar{\eta} \pmod{p} \), which in turn, after multiplying by \( \bar{\beta} \), is equivalent to 
\( (N\beta)\eta \equiv \bar{x} \bar{\eta} \pmod{p} \); now \( \beta \) and \( \bar{\eta} \) are fixed and, since \( p \) does not divide \( \beta \), each of the \( p^2 \) possible \( \bar{\eta} \) values yields a unique \( \eta \); thus there are exactly \( p^2 \) solutions 
\[ x = \eta + \bar{\xi} \pi \bar{\eta} \text{ of } \alpha x \equiv 0 \pmod{p} \].

iv) Each prime \( \pi \) in \( \mathbb{L} \) with \( N\pi = p \) gives rise to one of the \( (p^2 - 1)(p-1) \) non-trivial solutions of \( N\alpha \equiv 0 \pmod{p} \), \( \alpha \equiv 0 \pmod{p} \); conversely to each such \( \alpha \) there is (see \( \#5(iii) \)) a prime \( \pi \) in \( \mathbb{L} \) with \( N\pi = p \); since
$\Pi \equiv 0 \pmod{p}$ has (see (iii-d)) exactly $p^2-1$ non-trivial solutions each $\Pi$ must arise from exactly $p^2-1$ different $\alpha$; thus there are $p+1 \left(=\frac{(p^2-1)(p+1)}{p^2-1}\right)$ distinct $\Pi$.

7. i) The presence of such a pair of consecutive factors means that

$$N(\Pi_{\eta} \Pi_{\eta+1}) = N(\Pi_{\eta} \bar{\Pi}_{\eta}) = p_\nu$$

so $p_\nu$ divides $\alpha$ and $\alpha$ is not primitive;

ii) the proof is by induction; the proposition is vacuously true for the case when the number of factors is 1; suppose the proposition true for $t-1$ factors and let $\alpha = \Pi_1 \ldots \Pi_t \equiv 0 \pmod{p}$ for some prime $p$ in $\mathbb{Z}$; if $\Pi_2 \ldots \Pi_t$ is not primitive the conclusion is true by (i) and the induction hypothesis; otherwise
\[ \bar{\pi}_1 \pi_1 \pi_2 \cdots \pi_t = (N \pi_1) \pi_2 \cdots \pi_t \equiv 0 \pmod{p} \]
and, therefore, \( N \pi_1 \equiv 0 \pmod{p} \); but then
\( N \pi_1 = p \); hence
\[ p \pi_2 \cdots \pi_t = \bar{\pi}_1 \pi_1 \pi_2 \cdots \pi_t = \bar{\pi}_1 p \beta, \]
for suitable \( \beta \); but then \( \pi_2 \cdots \pi_t = \bar{\pi}_1 \beta \) and, by \( \#5 \)(x), \( \pi_2 \) and \( \bar{\pi}_1 \) are associates;

\( iii \)) in the product \( \pi_1 \cdots \pi_{\alpha_v} \), there are \( p_{\alpha_v} + 1 \) choices for \( \pi_{\alpha_v} \) by \( \#6 \)(iv), and for each other \( \pi_{\alpha_j} \) there are only \( p_{\alpha_j} \) choices; since, by (ii), consecutive factors may not be conjugates; the multiplier \( \beta \) comes from the possible \( \beta \) factors which are the units in \( \mathbb{L} \);

\( iv \)) by (ii) a non-primitive \( \alpha \) will have consecutive factors one of which is an associate of the other; each square which is a divisor of \( m \) arises from a
collection of disjoint such pairs; thus if $d^2 | m$ then associated with this $d$ there are, by $(\text{iwi})$, $8 \frac{m}{d^2} \prod_{p | m} (1 + \frac{1}{p})$ primitive elements of $\mathcal{L}$ of norm $\frac{m}{d^2}$, each of which when multiplied by $d^2$ yields an $\alpha$ in $\mathcal{L}$ of norm $m$; the total number of such $\alpha$ is just the left hand side of the indicated expression; now, for each $d | m$ if we let $d'$ be the largest square factor of $\frac{m}{d}$ we find

$$\sigma(m) = \sum_{d | m} d = \sum_{d | m} \sum_{t | d', t \text{ squarefree}} \frac{m}{d^2} \quad \frac{m}{d^2} \sum_{t | d', t \text{ squarefree}} \frac{1}{t}$$

$$= \sum_{d | m} \frac{m}{d^2} \prod_{p | m} (1 + \frac{1}{p})$$

where $t$ is squarefree throughout;

v) there are 24 elements of $\mathcal{L}$ of norm 2 (see $\ast 6(i)$) and they are merely permuted by multiplication by the 8 units of $\mathcal{L}$; thus, by $(\text{iv})$, we have $24 \sigma^0(n)$ such $\alpha$;
vi) since \( N\alpha \) is a sum of 4 squares for every \( \alpha \) in \( \mathcal{C} \) the desired number of solutions may be obtained from (iv) and (v) ; let \( M \) be the number of divisors of \( n \) not divisible by 4 ; if \( n \) is odd then \( M = \sigma(m) \) by (iv) and the number of \( \alpha \) is \( 8M \) ; if \( n \) is even then \( M = \sigma^*(n) + 2\sigma^*(n) = 3\sigma^*(n) \) and by (v) the number of \( \alpha \) is \( 8M \).

8. We sketch the argument in 7 steps.

i) \( G \) has exactly 4 units ;

ii) \( \#5(\text{iv}) \) is replaced by : rational primes of the form \( 4k+3 \) are primes in \( G \); no other rational primes are primes in \( G \) but each is the norm of a prime in \( G \);

iii) \( \#5(\text{v}) \) is replaced by : \( \alpha \) primitive and prime in \( G \) implies \( N\alpha \) is prime in \( \mathbb{Z} \);
w) #5 (viii) remains the same but it should be noted that if \( \alpha \) is primitive and an odd prime divides \( N\alpha \) then that prime is of the form \( 4k+1 \); this implies that \( N\alpha \), for \( \alpha \) in \( G \), can never have an odd power of a \( 4k+3 \) prime in its canonical prime factorization;

v) #5 (x) is replaced by: if \( \alpha \) in \( G \) is such that \( N\alpha = 2^r q_1^2 \cdots q_t^2 p_1 \cdots p_s \), where the \( q_v \) are \( 4k+3 \) primes and the \( p_v \) are \( 4k+1 \) primes then there exist unique, up to associates, primes \( \Pi_1, \ldots, \Pi_s \) in \( G \) such that \( \alpha = (1+i)^r q_1 \cdots q_t \Pi_1 \cdots \Pi_s \), \( N\Pi_v = p_v \) for \( 1 \leq v \leq s \);

vi) the methods of #6 may be used to prove: the number of distinct, up to associates, solutions of \( N\alpha \equiv 0 \pmod{p} \), where \( p \) is an odd prime in \( \mathbb{Z} \), is \( 0 \) or \( p \) depending on whether \( p \) is a \( 4k+3 \) or a
4k+1 prime, while the number of solutions of $N \alpha = p$, again up to associates, is 1;

(vii) from $n = 2^r q_1^2 \cdots q_s^2 p_1 \cdots p_s$, where the $q_i$ and $p_j$ are as in (v), we may write

$$n = (1+i)^r (1-i)^r \prod q_i^{v_i} \prod (a+ib)^{\nu_i} (a-ib)^{\nu_i}$$

$$= A^2 + B^2 = (A+iB)(A-iB)$$

and so, by unique factorization

$$A+iB = i^\alpha (1+i)^{ri} (1-i)^{ri} \prod q_i^{v_1} \prod (a+ib)^{\nu_1} (a-ib)^{\nu_1},$$

$$A-iB = (-i)^\alpha (1+i)^{ri} (1-i)^{ri} \prod q_i^{v_2} \prod (a+ib)^{\nu_2} (a-ib)^{\nu_2},$$

where $v_1 + v_2 = 2v$; from this we see $v_1 = v_2$ and, since $1+i$ and $1-i$ are associates, the number of possible pairs $A, B$ is just the number $\prod (N+1)$ of divisors of $\prod p^\nu$; the sum of all odd divisors of $n$ is

$$\prod (1+q+\cdots+q^{2v}) \prod (1+p+\cdots+p^{\nu})$$

replacing each $q$ by $-1$ and each $p$ by 1 yields, on the one hand $\prod (N+1)$, and, on the other hand, $d_1(m) - d_3(m)$. 

9. i - a, b) These follow from the fact that the product of 2 odd numbers is of the form \( 4k + 3 \) if and only if exactly one of them is of the form \( 4k + 3 \);

\[ f_2(ab) = \frac{1}{4} r_2(ab) = d_4(ab) - d_3(ab) \]
\[ = d_1(a)d_1(b) + d_3(a)d_3(b) - d_3(a)d_1(b) - d_1(a)d_3(b) \]
\[ = (d_1(a) - d_3(a))(d_1(b) - d_3(b)) = \frac{1}{4} r_2(a) - \frac{1}{4} r_2(b) \]
\[ = f_2(a)f_2(b) \]

ii-a) this is a restatement of Jacobi's theorem;

b) let \((a, b) = 1\) then using (a) and the multiplicativity of \(\sigma\) we have:

for \(ab\) odd,

\[ f_4(ab) = \frac{1}{8} r_4(ab) = \sigma(ab) = \sigma(a)\sigma(b) \]
\[ = \frac{1}{8} r_4(a) + \frac{1}{8} r_4(b) = f_4(a)f_4(b) \]
while for $ab$ even (without loss of generality take $a$ even, $b$ odd)

$$f_4(ab) = \frac{1}{8} r_4(ab) = 3\sigma(ab) = 3\sigma(a)\sigma(b)$$

$$= 3 \cdot \frac{1}{24} r_4(a) \cdot \frac{1}{8} r_4(b) = f_4(a) f_4(b) ;$$

\[\text{iii-a) if } 2 = a_1^2 + \cdots + a_s^2 \text{ then } s \geq 2 \text{ and all } a_j \text{ except for } 2 \text{ must be } 0; \text{ the } 2 \text{ which are not } 0 \text{ are each either } \pm 1; \text{ thus the total number of solutions is } 4 \text{ times the number of pairs of the } a_j \text{ which may be taken to be non-zero;}

b) similar to (a) ;

c) if $6 = a_1^2 + \cdots + a_s^2$ then $s \geq 3$ and either 6 of the $a_j$ are $\pm 1$ or 2 of the $a_j$ are $\pm 1$ and 1 other is $\pm 2$; the total number of ways of doing this is

$$2^6 \left( \binom{5}{6} \right) + 3 \cdot 2^3 \left( \binom{5}{3} \right) = 64 \left( \binom{5}{6} \right) + 24 \left( \binom{5}{3} \right) ;$$
d) \[ f_s(6) - f_s(2)f_s(3) = \]
\[ \frac{1}{25} (64\left(\frac{5}{6}\right) + 24\left(\frac{5}{3}\right) - 32\left(\frac{5}{2}\right)\left(\frac{5}{3}\right)) \]
\[ = \frac{2}{45} s(s-1)(s-2)(s-4)(s-8) ; \]

e) If \( f_s \) were multiplicative then \( f_s(6) - f_s(2)f_s(3) \) would have to be 0; but, by (d), this can happen only for \( s = 1, 2, 4, 8 \).
Convolution Theorem - Solutions

1. Let $n, n+2$ be primes, $1 < n < \sqrt{x}$; the number of such pairs with $n \leq x$ is less than or equal to $x$ and each pair with $n \geq x$ has $(a_n, R) = 1$ so contributes 1 to $S$. Hence $\Pi_2(x) \leq x + S$.

2. Suppose $a_n = d'd'$, where $d' | R$ and $(d', R) = 1$; if $d' = 1$ then $(a_n, R) = 1$ and $n$ contributes 1 to $S_1$ and 0 to $S_\delta$, $\delta \neq 1$, so $n$ contributes 1 to the right hand side of the given expression; on the other hand if $d' = p_1 \cdots p_j$, $1 \leq j \leq 2k$, then $n$ contributes 1 to each of the $\left( \begin{array}{c} i \end{array} \right)$ terms $S_\delta$, where $\delta | d'$, $\forall (\delta) = i$; thus $n$ contributes

$$1 - \left( \frac{1}{i} \right) + \left( \frac{1}{2} \right) - \left( \frac{1}{3} \right) + \cdots + (-1)^i \left( \frac{1}{i} \right) = (i-1)^i = 0$$

to the right hand side.

3. When $p$ is odd exactly two, namely the last and third last, of the numbers
are divisible by $p$, while when $p=2$ only the last is divisible by $p$; thus when $v(\mathfrak{d})=1$ the expressions for $p(\mathfrak{d})$ are correct; assume them to be correct for $v(\mathfrak{d})=n$ and examine $v(\mathfrak{d}p)$, where $\mathfrak{d}p | R, p\nmid \mathfrak{d}$, and, as we may assume without loss of generality, $p$ is odd; now $pi+j$, $1 \leq i \leq \mathfrak{d}$, $1 \leq j \leq p$ is a complete system of residues modulo $\mathfrak{d}p$ so we wish to find the number of solutions of

$$(pi+j)(pi+j+2) \equiv 0 \pmod{\mathfrak{d}p};$$

the number of solutions of this congruence is equal to the number of solutions of the system

$$(pi+j)(pi+j+2) \equiv 0 \pmod{p},$$

$$(pi+j)(pi+j+2) \equiv 0 \pmod{\mathfrak{d}};$$

from the $1^{st}$ congruence we see that

$$j(j+2) \equiv 0 \pmod{p}$$

and hence there are exactly $2$ values of $j$ possible; for each of these $2$ values of $j$ the numbers $pi+j$, $1 \leq i \leq \mathfrak{d}$, constitute a complete
system of residues modulo \( \delta \) so the number of solutions of the 2\textsuperscript{nd} congruence is \( \rho(\delta) \); therefore the number of solutions of the system is \( 2\rho(\delta) \); this gives \( \rho(\delta \rho) = 2^{\sqrt{(\delta \rho)} - \varepsilon} \), where \( \varepsilon \) is 0 or 1 depending on whether \( \delta \rho \) is odd or even; this completes the induction.

4. Let \( x = q\delta + r, 0 \leq r < \delta \); then the numbers \( n, 1 \leq n \leq [x] \) fall either into one of \( q \) complete systems of residues modulo \( \delta \) or into a remaining partial system of residues modulo \( \delta \); the total number of \( n \) with \( \delta \mid a_n \) is \( S_\delta \) while the number in each complete system of residues is \( \rho(\delta) \); thus there is a \( \sigma_1, 0 \leq \sigma_1 < 1 \), such that

\[
S_\delta = q \rho(\delta) + \sigma_1 \rho(\delta)
\]

\[
= (\frac{\sigma}{\delta} + \sigma_1 - \frac{r}{\delta}) \rho(\delta);
\]

putting \( \theta = \sigma_1 - \frac{r}{\delta} \) yields the desired result.
5. Using *2 and *4 we find
\[ S = \sum_{\delta R, \nu(\delta) \leq 2k} (-1)^{\nu(\delta)} \left( \frac{x}{\delta} + \delta \right) \rho(\delta) \]
\[ = \sum_{\delta R, \nu(\delta) \leq 2k} (-1)^{\nu(\delta)} \rho(\delta) + \sum_{\delta R, \nu(\delta) \leq 2k} \delta (-1)^{\nu(\delta)} \rho(\delta) \]
\[ = \sum_{\delta R, \nu(\delta) \leq 2k} (-1)^{\nu(\delta)} \rho(\delta) - \sum_{\delta R, \nu(\delta) > 2k} \delta (-1)^{\nu(\delta)} \rho(\delta) + \sum_{\delta R, \nu(\delta) \leq 2k} \delta (-1)^{\nu(\delta)} \rho(\delta) \]
\[ \leq \sum_{\delta R, \nu(\delta) \leq 2k} (-1)^{\nu(\delta)} \rho(\delta) + \sum_{\delta R, \nu(\delta) \geq 2k} \delta (-1)^{\nu(\delta)} \rho(\delta) + \sum_{\delta R, \nu(\delta) \leq 2k} \rho(\delta) \]
\[ = x \left( T_1 + T_2 \right) + T_3 \]

the alternate expression for \( T_4 \) is a direct consequence of \#3 as is the inequality in the expression for \( T_2 \); finally, since the number of \( \delta \) such that \( \nu(\delta) = j \) and \( \delta | R \) is just \( \binom{\nu(R)}{j} \), where \( \nu(R) = \Pi(3) \), we have
\[ T_3 = \sum_{j=0}^{2k} \sum_{\delta R, \nu(\delta) = j} \rho(\delta) \leq \sum_{j=0}^{\Pi(3)} \binom{\nu(3)}{j} 2^j. \]

6. By \( \nu(4) \), there is a constant \( C \) such that \( C n \ln n < p_n \) for all \( n \); thus
\[ \sum_{p \leq t} \frac{1}{p} \leq \sum_{n \geq 2} \frac{1}{c n \ln n} \leq \frac{1}{C} \left( 1 + \int_2^t \frac{1}{x \ln x} \, dx \right) < A \ln \ln t \]
for suitable positive \( A \) with \( eA \ln 2 > 1 \).
7. The last 2 inequalities are clearly true for \( x \) sufficiently large; the 1st follows from the fact that as \( x \to \infty \) so also does \( \delta \) plus the fact that the left side is of the order of \( \ln \ln \delta \) while the right side (see XIV* 10 (ix)) is of the order of \( \frac{\delta}{\ln \ln \delta} \).

8. Using *7,*

\[
4 < \ln \delta = \frac{\ln x}{\infty \ln \ln x} < \frac{\ln x}{18} < \ln \sqrt{x}
\]

so \( 2 < \delta < \sqrt{x} \); further, \( 2k \leq \pi (\delta) = \nu (R) \).

9. In (a) the 1st inequality follows from *5(a) and \( 1 - \frac{2}{\rho} < (1 - \frac{1}{\rho})^2 \), the 2nd inequality from

\[
\prod_{\rho \in \mathbb{R}} (1 - \frac{1}{\rho})^{-1} = \prod_{\rho \in \mathbb{R}} (1 + \frac{1}{\rho} + \frac{1}{\rho^2} + \cdots) \geq \sum_{m=1}^{\infty} \frac{1}{m}
\]

and the 3rd inequality from the fact \( \sum_{m=1}^{\infty} \frac{1}{m} > \int_{1}^{\infty} \frac{1}{x} \, dx \) ;

in (b) the 1st inequality follows from *5(b) and

\[
\sum_{\nu | \delta = j} \frac{1}{\delta} \leq \left( \sum_{p \leq \delta} \frac{1}{p} \right)^j \frac{1}{j!}, \text{ the 2nd inequality from *6 and the fact that } \frac{j^j}{j!} < 1 + \frac{j^2}{2!} + \cdots + \frac{j^j}{j!} + \cdots = e^j,
\]
the 3rd inequality from $2eA \ln \ln x < k < \frac{1}{2}$ and

$$\sum_{j=2^{k+1}}^{\infty} \left( \frac{1}{2} \right)^j = 2^{-2^k},$$

the 4th inequality from 6 and

$k \ln 2 > 2eA \ln 2 \ln \ln x > \ln \ln x$.

In (c) the 1st inequality follows from 5(c) and

$$\left( \frac{\ln(3)}{3} \right)^j \leq \frac{(\ln(3))^j}{j!} \leq \frac{(\ln(3))^{2^k}}{j!},$$

the 2nd and 3rd inequalities from

$$\sum_{j=0}^{2^k} \frac{2^j}{j!} < \sum_{j=0}^{\infty} \frac{2^j}{j!} = e^2 < 9 \text{ and } \Pi(3) < 3.$$

10. From the definitions of 3 and 5 given in 7 and 8 we see

$$\ln 3 = \frac{\ln x}{6eA \ln \ln x}, \quad \ln \ln 3 = \ln \ln x - \ln \ln \ln x = \ln 6eA$$

and, therefore,

$$\frac{1}{(\ln 3)^2} = (6eA)^2 \left( \frac{\ln x}{\ln x} \right)^2,$$

$$3^{2k} = x^{2k \ln 3} \leq x^{2eA \ln \ln x} = x^{2 - \frac{2}{3} \ln \ln x - \frac{2}{3} \ln 6eA} = x^\beta;$$

thus, using 1, 5, 8, 9 we find

$$\Pi_2(x) \leq \Pi_3 \leq x + x(T_1 + T_2) + T_3 \leq \sqrt{x} + x \frac{B+1}{(\ln 3)^2} + 9 \cdot 3^{2k}$$

$$\leq \sqrt{x} + x(6eA)^2 (B+1) \left( \frac{\ln x}{\ln x} \right)^2 + x^\beta < Cx \left( \frac{\ln x}{\ln x} \right)^2$$

for suitable positive $C$ and $x$ sufficiently large.
11. For \( x \) sufficiently large

\[ \pi_2(x) < Cx \left( \frac{\ln \ln x}{\ln x} \right)^2 < \frac{C x}{(\ln x)^{3/2}} \]

thus if \( p_n \) is the \( n \text{th} \) prime for which \( p_n + 2 \) is prime then

\[ n = \pi_2(p_n) < \frac{C p_n}{(\ln p_n)^{3/2}} < \frac{C p_n}{(\ln n)^{3/2}} \]

so \( \frac{1}{p_n} < \frac{C}{n(\ln n)^{3/2}} \) and the result in (a) follows immediately by the comparison

\[ \sum \frac{1}{p_n} < \sum \frac{C}{n(\ln n)^{3/2}} \]

and the convergence of the right hand series;

(b) follows from (a) by splitting \( \sum \frac{1}{p_n} \) into the sum in (a) and a sum dominated by the sum in (a).
xvii Quadratic Residues ~ Solutions

1. i) Multiplying the 1st congruence by 4a leads to the equivalent congruence

$$4af(x) \equiv 0 \pmod{4am};$$

since $$4af(x) = (2ax + b)^2 - D$$ the result follows;

ii) suppose (a) is true and $$x_0^2 \equiv a \pmod{m},$$
where $$a = a'd, m = m'd.$$ Then, since $$s^2 \mid x_0^2,$$
$$x_0 = sy_0$$ for suitable $$y_0.$$ Thus $$y_0^2 \equiv a't \pmod{m't}$$
and, therefore, $$t$$ divides $$y_0^2.$$ But $$t$$ is squarefree
so $$t$$ divides $$y_0$$ and $$y_0 = ts$$ for suitable $$s.$$ This
means $$ts^2 \equiv a' \pmod{m'}.$$ Since any common
prime factor of $$t$$ and $$m'$$ would divide $$a'$$ and $$a', m' = 1,$$ we must have $$(t, m') = 1.$$ Hence
$$ts^2 \equiv a' \pmod{m'}$$ and $$(ts)^2 \equiv ta' \pmod{m'}$$ are
equivalent. This proves (a) implies (b).
Suppose now (b) is true and \(x_0^2 \equiv ta' \pmod{m'}\). Since \((t, m')=1\) there is an \(s\) such that \(x_0 \equiv ts \pmod{m'}\). Thus \(t^2s^2 \equiv ta' \pmod{m'}\) and, since \((t, m')=1\) this last congruence implies (indeed, is equivalent to) the congruence \(ts^2 \equiv a' \pmod{m'}\). Multiplying by \(t\delta^2 (= \delta)\) we obtain \((t\delta s)^2 \equiv a \pmod{m}\). Thus (b) implies (a).

2. i) If \(x_0^2 \equiv 12 \pmod{45}\) then \(3 \mid x_0\); but then since \(3^2 \mid 45\), we would have to have \(3^2 \mid 12\), contrary to fact;

ii) taking \(a = 252 = 2^2 \cdot 3^2 \cdot 7\), \(m = 3^2 \cdot 5^2 \cdot 7\) in *1(ii) we find \(t = 7, \delta = 3^2 \cdot 7\) and \((t, \frac{m}{\delta}) = (7, 25) = 1\); thus \(x^2 \equiv 252 \pmod{1575}\) is equivalent to
\[x^2 \equiv 28 \equiv 3 \pmod{25}\).

3. i-a) In this case the congruence becomes \(x^2 \equiv 1 \pmod{2}\); thus, modulo 2, there is exactly 1 solution;
6) In this case \( x^2 \equiv a \pmod{4} \); since \((a, 4) = 1\), modulo 4, \(x\) must be either 1 or 3; in either case \( x^2 \equiv 1 \pmod{4} \); thus \(a \equiv 1 \pmod{4}\); on the other hand if \(a \equiv 1 \pmod{4}\) then \(x = 1, x = 3\) are both solutions;

c) see the proof of (6);

d) since \(a\) must be odd so also must \(x\) be odd; but the square of every odd number is congruent to 1 (mod 8) (see IX*8(i1)); on the other hand if \(a \equiv 1 \pmod{8}\) then all possible odd \(x\) satisfy \(x^2 \equiv a \pmod{8}\) since each of 1, 3, 5, 7 satisfies the congruence;

e) it is clear that solvability of \((*_{a+1})\) implies solvability of \((*_{a})\); thus, suppose \((*_{a})\) is solvable and that \(x_0\) is a solution; then \(x_0\) is odd and \(x_0^2 = a + 2^r \cdot t\) for suitable \(t\); choosing \(s\) so that
\( t + x_0s \equiv 0 \pmod{2} \) we see that

\[
(x_0 + s \cdot 2^{\alpha-1})^2 = x_0^2 + x_0s 2^\alpha + s^2 \cdot 2^{2\alpha-2}
\]

\[= a + (t + x_0s)2^\alpha + s^2 \cdot 2^{2\alpha-2} \equiv a \pmod{2^{\alpha+1}},
\]

where the last congruence is true since

\[2^\alpha - 2 = \alpha + (\alpha - 2) \geq \alpha + 1 \text{ when } \alpha \geq 3;
\]
thus solvability of \((x_0)\) implies solvability of \((x_{\alpha+1})\);

\[f) \text{ if } x_0^2 \equiv a \equiv y_0^2 \pmod{2^\alpha} \text{ then }
(x_0 + y_0)(x_0 - y_0) \equiv 0 \pmod{2^\alpha};
\]
since \(x_0, y_0\) are odd exactly one of the even integers \(x_0 + y_0, x_0 - y_0\) is divisible by 4; hence \(x_0 \equiv \pm y_0 \pmod{2^{\alpha-1}}\); thus there are at most the 4 solutions \(x_0, -x_0, x_0 + 2^{\alpha-1}, -x_0 + 2^{\alpha-1}\); since, when \(x_0\) is a solution, all of these are solutions and since they are pairwise incongruent modulo \(2^\alpha\) this proves there are exactly 4 solutions;

\[g) \text{ this follows from (a)-(f).} \]
ii-a) from \( x^2 \equiv a \equiv y^2 \pmod{p} \) we conclude 
\( x \equiv \pm y \pmod{p} \); thus there are exactly the 
2 incongruent solutions \( x, -x \) when \( x \) is a 
solution;

b) let \( x_0^2 = a + kp^\alpha \) and note that \((2x_0,p)=1\); 
thus there is exactly one \( t \), modulo \( p \), value of 
t such that \( k + 2x_0t \equiv 0 \pmod{p} \) and for this 
t we have \((x_0 + tp^\alpha)^2 = x_0^2 + 2x_0tp^\alpha + t^2p^{\alpha+1} = a + (k + 2x_0t)p^\alpha + t^2p^{\alpha+1} \equiv a \pmod{p^{\alpha+1}}\);

c) this follows immediately from (b);

d) if \( x^2 \equiv a \equiv y^2 \pmod{p^\alpha} \) then, since \( p \) 
divides neither \( x \) nor \( y \), the quantities \( x+y \), 
\( x-y \) are not both divisible by \( p \); hence 
\( x \equiv \pm y \pmod{p^\alpha} \); this shows there are at most 
2 solutions; since \( -x \) also is a solution when \( x \) 
is a solution and since \( x \neq -x \pmod{p} \) this 
completes the proof;
iii) since every solution of the system is a solution of each individual congruence, \( N > 0 \) implies \( N_j > 0 \) for all \( j \), \( 1 \leq j \leq r \); different, modulo \( m_1 \cdots m_r \), solutions of the system lead to different \( r \)-tuples of solutions to the individual congruences since if \( x \equiv x' \pmod{m_j} \) for all \( j \), \( 1 \leq j \leq r \), then \( x \equiv x' \pmod{m_1 \cdots m_m} \); hence \( N \leq N_1 \cdots N_r \); on the other hand if \( x_1, \ldots, x_r \) is an \( r \)-tuple solution for the \( r \) congruences (i.e. \( x_j \) is a solution to the \( j \)th congruence) then if \( t_1 \frac{m_1 \cdots m_r}{m_j} \equiv 1 \pmod{m_j} \), \( 1 \leq j \leq r \), we have \( x = x_1 t_1 \frac{m_1 \cdots m_r}{m_j} + \cdots + x_r t_r \frac{m_1 \cdots m_r}{m_r} \) a solution of the system; finally if \( x'_1, \ldots, x'_r \) is a different \( r \)-tuple solution for the \( r \) congruences, \( x' = x_1 t_1 \frac{m_1 \cdots m_r}{m_j} + \cdots + x_r t_r \frac{m_1 \cdots m_r}{m_r} \) is not congruent, modulo \( m_1 \cdots m_r \), to \( x \) since otherwise for all \( j \), \( 1 \leq j \leq r \), \( x_j \equiv x'_j \pmod{m_j} \); hence \( N_1 \cdots N_r \leq N \); the conclusion follows;
\( w - a \) this follows from (iii), (i-b), \( c \equiv (i-d) \);

b) this follows from (iii), (i-g), (ii-d) \( c \equiv (a) \).

4. i) By Fermat's theorem (\( a^{p-1} + 1 \equiv a^{p-1} \equiv 0 \pmod{p} \)); consequently \( a^{p-1} \equiv \pm 1 \pmod{p} \);

since \( p \) is odd not both are possible since that would imply \( 2 \equiv 0 \pmod{p} \);

ii) from \( x_0^2 \equiv a \pmod{p} \) we find

\[
a^{p-1} \equiv x_0^{p-1} \equiv 1 \pmod{p} ;
\]

iii-a) by the remainder theorem in algebra we know \( z^{p-1} - 1 = (z - a) q(z) + a^{p-1} - 1 \),

where \( q \) is a polynomial of degree \( p-1 \) \( \equiv p-3 \);

replacing \( z \) by \( x^2 \) yields the result ;

b) immediate from (a) and Fermat's theorem;
\( w \) if \( a \) is a QR of \( p \) then, by \((\text{ii})\),
\[ a^{p-1} \equiv 1 \pmod{p}; \]
on the other hand if \( a^{p-1} \equiv 1 \pmod{p} \) then, by
\((\text{iii-6})\), since \( q(x^2) \) is of degree \( p-3 \) in \( x \) and hence not always congruent to 0 modulo \( p \),
there is an \( x \) for which \( x^2 - a \equiv 0 \pmod{p} \); i.e.
a is a QR of \( p \); the rest follows from \((i)\).

5. \( i \) Since \( x = a \) satisfies \( x^2 \equiv a^2 \pmod{p} \) it is clear that \( \left( \frac{a^2}{p} \right) = 1; \)

\( \text{ii} \) immediate from \#4 \((\text{iv})\) and the definition of \( \left( \frac{a}{p} \right) \);

\( \text{iii} \) \( \left( \frac{a}{p} \right) \equiv a^{p-1} \equiv b^{p-1} \equiv \left( \frac{b}{p} \right) \pmod{p} \); since
\( \left( \frac{a}{p} \right) \) and \( \left( \frac{b}{p} \right) \) are \( \pm 1 \) and since \( 1 \equiv -1 \pmod{p} \)
this means \( \left( \frac{a}{p} \right) = \left( \frac{b}{p} \right) ; \)
\[ \begin{align*} 
& \text{iv) } \left( \frac{ab}{p} \right) \equiv (ab) \left( \frac{1}{2} \right) \left( \frac{p-1}{2} \right) \left( \frac{p-1}{2} \right) \equiv (\frac{a}{p})(\frac{b}{p})(\frac{p-1}{2})(\mod p); \\
& \quad \text{as in (iii), } \left( \frac{ab}{p^2} \right) = \left( \frac{a}{p} \right)(\frac{b}{p}); \\
& \\text{v) a) if } a^2 \equiv b^2 \pmod{p} \text{ then } a \equiv \pm b \pmod{p}, \\
& \quad \text{which cannot happen because of the conditions on } a \text{ and } b; \\
& \quad \text{b) for } 0 < a < p-1 \text{ there is a non-zero number } c, -\frac{p-1}{2} < c < \frac{p-1}{2} \text{ with } a \equiv c \pmod{p}; \text{ putting } \\
& \quad b = |c| \text{ yields the desired result}; \\
& \quad \text{c) immediate from (6) and the meaning } \\
& \quad \text{of } \left( \frac{a}{p} \right) = 1; \\
& \quad \text{vi) } \left( \frac{-1}{p} \right) \equiv (-1) \left( \frac{p-1}{2} \right) \pmod{p}, \text{ by (ii)}; \text{ since both } \\
& \quad \text{sides are } \pm 1 \text{ and } p \text{ is odd this implies the equality.} \\
& \quad \text{6. i) From } \#5 \text{ (i)}; \\
& \quad \text{ii) from } \#5 \text{ (i\text{ii})}; 
\end{align*} \]
iii) from \#5 (iv); 

iv) by the proof of IX \#20 (i - a) we know a polynomial of degree \( n \) may have no more than \( n \) zeros modulo \( p \); thus \( x^{\frac{p-1}{2}} \equiv 1 \) and \( x^{\frac{p^2-1}{2}} \equiv -1 \) (mod \( p \)) each has at most \( \frac{p-1}{2} \) solutions; since all the integers \( 1, 2, \ldots, p-1 \) satisfy exactly one of these congruences each must have exactly \( \frac{p-1}{2} \) solutions; the conclusion now follows from \#4 (iv).

7. i) Let \( n = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \); since \( (\frac{n}{p}) = -1 \) we know \( p \mid n \) so, by \#5 (iv), \( (\frac{n}{p}) = (\frac{p_1}{p})^{\alpha_1} \cdots (\frac{p_k}{p})^{\alpha_k} = -1 \); thus for some \( j \), \( \alpha_j \) is odd and \( (\frac{p_j}{p}) = -1 \); this implies, for such a \( j \), \( \sum_{d \mid p_j^{\alpha_j}} (\frac{d}{p}) = 0 \); but then, see VIII \#27,

\[
\sum_{d \mid n} d^{\frac{p-1}{2}} = \prod_{i=1}^{k} \sum_{d \mid p_i^{\alpha_i}} d^{\frac{p^2-1}{2}} \equiv \prod_{i=1}^{k} \sum_{d \mid p_i^{\alpha_i}} (\frac{d}{p}) = 0 \pmod{p},
\]

where we have also used \#5 (ii); 

ii) this is merely a rephrasing of \#6 (iv).
iii-a) Since, by \( #5(\text{i}) \), \((\frac{a_5}{p}) = (\frac{a}{p})(\frac{b}{p})\) not all three of these Legendre symbols may be -1.

\[5)\] Since \( x^6 - 11x^4 + 36x^2 - 36 = (x^2 - 2)(x^2 - 3)(x^2 - 6) \)
and since, by (a), one at least of 2, 3, 6 is a qr modulo any prime other than 2 and 3 the conclusion follows as soon as we observe that 2 and 3 divide the value of this polynomial when \( x = 0 \).

\(\text{i})\) From \( ax_0^2 \equiv -6y_0^2 \pmod{p} \), using \#5(i), \#5(iii), and \#5(i) we see that
\[(\frac{a}{p}) = (\frac{ax_0^2}{p}) = (\frac{-6y_0^2}{p}) = (\frac{-6}{p}).\]

\(8.\ i)\) By \#5(v) every qr of \( p \) is congruent to exactly one of \( 1^2, 2^2, \ldots, (\frac{p-1}{2})^2 \); since, by \#6(i), there are exactly \( \frac{p-1}{2} \) qr of \( p \) we see, using Wilson's theorem,
\[
\prod_{a \equiv 1 \pmod{p}}^{} a = 1^2 \cdot 2^2 \cdots (p-1)^{p-1} \equiv (-1)^{p-1} \cdot 1 \cdot 2 \cdots \frac{p-1}{2} \cdot (-\frac{p-1}{2}) \cdots (-1) \\
\left( \frac{p}{q} \right)_{q=1} \equiv (-1)^{\frac{p-1}{2}} \cdot (p-1)! \equiv \left( -\frac{1}{p} \right)(p-1)! \equiv -\left( \frac{-1}{p} \right) \pmod{p};
\]

the other conclusion follows from
\[
-\left( \frac{-1}{p} \right) \prod_{a \equiv 1 \pmod{p}}^{} a \equiv \left( \prod_{a \equiv 1 \pmod{p}}^{} a \right) \left( \prod_{a \equiv 1 \pmod{p}}^{} a \right) \equiv (p-1)! \equiv -1 \pmod{p};
\]

\[\left( \frac{-1}{p} \right)_{q=1} \equiv \left( \frac{-1}{p} \right)(p-1)! \equiv -1 \pmod{p};\]

\[\left( \frac{-1}{p} \right)_{q=1} \equiv \left( \frac{-1}{p} \right)(p-1)! \equiv -1 \pmod{p};\]

ii) a) When \( p \equiv 1 \pmod{4} \), \( \frac{p-1}{2} \) is even;

consequently, when \( a^{p-1} \equiv 1 \pmod{p} \) so also is

\((-a)^{p-1} \equiv 1 \pmod{p} \); this implies the desired result;

b) When \( p \equiv 3 \pmod{4} \), \( \frac{p-1}{2} \) is odd;

consequently when \( a^{p-1} \equiv 1 \pmod{p} \) then

\((-a)^{p-1} \equiv -1 \pmod{p} \); this implies the desired result;

c) Immediate from (a);

d) The 1st part of (i) combined with (a)

and (b) yield these results.
9. (i) \(|a_i| = |a_j|\) implies \(u \equiv a_i = \pm a_j \equiv \pm j a \pmod{p}\) which implies \((i \pm j)a\) is divisible by \(p\); but \(1 \leq i < j \leq \frac{p-1}{2}\) precludes \(i \pm j\) being divisible by \(p\) and we are given \(p \nmid a\); the conclusion follows.

(ii) The equality follows immediately from (i) and the congruence follows from the congruences \(a_i \equiv ia \pmod{p}\), \(1 \leq i \leq \frac{p-1}{2}\);

(iii) Immediate from (ii).

10. (i) Since \(v\) is the number of numbers among 2, 4, \(\cdots\), 2j, \(\cdots\), p-1 which have negative least absolute residues the result is clear.

(ii) By iv \(\neq 11\) and (i), \(v = \left[\frac{p}{2}\right] - \left[\frac{p}{4}\right]\);

If \(p = 8k + 1\) then

\[
\left[\frac{p}{2}\right] - \left[\frac{p}{4}\right] \equiv \left[\frac{i}{2}\right] - \left[\frac{i}{4}\right] \equiv \begin{cases} 0 \pmod{2} & \text{if } i = 1 \text{ or } 7; \\ 1 \pmod{2} & \text{if } i = 3 \text{ or } 5; \end{cases}
\]
iii) this follows from, when \( p = 8k + i \),

\[
\frac{p^2 - 1}{8} = \frac{64k^2 + 16ki + i^2 - 1}{8} \equiv \frac{i^2 - 1}{8} \equiv \begin{cases} 0 & \text{if } i = \pm 1 \\ 1 & \text{if } i = \pm 3 \end{cases} = \nu ;
\]

iv) this follows from (ii) (or (iii)) and the Lemma of Gauss.

11. i) Since \( \nu \) is the number of numbers among

3, 6, \ldots, 3j, \ldots, \frac{3}{2}(p - 1) \) which have negative least absolute residues and since only those between

\( \frac{p}{2} \) and \( p \) have this property the result is clear;

ii) the proof is similar to the proof of \#10(ii);

iii) this follows from (ii) and the Lemma of Gauss.

12. i) The number of 5, 10, \ldots, 5j, \ldots, \frac{5}{2}(p - 1) with negative least absolute residues modulo \( p \) is just

the number of \( j \) indicated.
ii) this follows from (i) ;

iii) this follows from (ii) and the Lemma of Gauss.

13. i) When \( p \equiv \pm q \pmod{4a} \) neither \( p \) nor \( q \) divides \( a \) so \( \left( \frac{a}{p} \right) = (-1)^v \), \( \left( \frac{a}{q} \right) = (-1)^w \), where

\[
V = \sum_{i = 1 \atop i \text{ even}}^a \left\{ \left[ \frac{i \cdot p}{2a} \right] - \left[ \frac{(i-1) \cdot p}{2a} \right] \right\}, \quad N = \sum_{i = 1 \atop i \text{ even}}^a \left\{ \left[ \frac{i \cdot q}{2a} \right] - \left[ \frac{(i-1) \cdot q}{2a} \right] \right\};
\]

if \( p = \pm q + 4a \) then

\[
V = \sum_{i = 1 \atop i \text{ even}}^a \left\{ \left[ \frac{iq}{2a} \right] + 2 \right\} - \left[ \frac{(i-1)q}{2a} \right] \equiv \sum_{i = 1 \atop i \text{ even}}^a \left\{ \left[ \frac{iq}{2a} \right] - \left[ \frac{(i-1)q}{2a} \right] \right\} \pmod{2};
\]

since for even \( j \) from \( 1 \) to \( a \) the quantity \( \frac{jq}{2a} \) is not an integer (if \( \frac{jq}{2a} = s \), since \( j \leq a, s \leq \frac{a}{2} \), so \( jq = 2as \) is impossible as \( q \) does not divide any of
\( 2, a, s \) ) the last sum is \( N \); thus \( V \equiv N \pmod{2} \)

and the result is proved;

ii) if \( p \equiv q \pmod{4} \) then \( p - q = 4a \) for suitable \( a \) and \( (a, pq) = 1 \); if \( p \not\equiv q \pmod{4} \) then one of
\( p, q \) is of the form \( 4k+1 \) and the other of the form \( 4k+3 \); thus their sum is of the form \( 4a \)
with \((a, pq) = 1\);

iii) making use of (i), (ii), and the properties
in #5 we have: for some \( a \), \( p = \pm q + 4a \), and,
therefore,
\[
\left( \frac{p}{q} \right) = \left( \frac{\mp q + 4a}{q} \right) = \left( \frac{4a}{q} \right) = \left( \frac{a}{q} \right) = \left( \frac{4a}{p} \right) = \left( \frac{-p + 4a}{p} \right) = \left( \frac{\mp q}{p} \right);
\]

iv) from (iii),
\[
\left( \frac{p}{q} \right) \left( \frac{q}{p} \right) = \begin{cases} 
\left( \frac{-1}{p} \right) & \text{if } p \equiv q \pmod{4} \\
1 & \text{otherwise}
\end{cases} = \begin{cases} 
\left( -1 \right)^{\frac{p-1}{2}} & \text{if } p \equiv q \pmod{4} \\
1 & \text{otherwise}
\end{cases} = (-1)^{\frac{p-1}{2}} \cdot \frac{q-1}{2}
\]

14. By the reciprocity law \( \left( \frac{p}{q} \right) \left( \frac{q}{p} \right) \) is 1, meaning
\( \left( \frac{p}{q} \right) = \left( \frac{q}{p} \right) \) except when each of \( p \) and \( q \) is of the form \( 4k+3 \) in which case \( \left( \frac{p}{q} \right) = -\left( \frac{q}{p} \right) \).
15. i) This is obvious;

ii) this is true since for each $p_j$ the Legendre symbols $(\frac{\alpha}{p_j})$ and $(\frac{\alpha^2}{p_j})$ are equal to 1;

iii) when $a$ is a qr of $m$ it is a qr of every $p_j$ and hence all $(\frac{\alpha}{p_j}) = 1$ which implies $(\frac{\alpha}{m}) = 1$;

iv) $(\frac{2}{3}) = (\frac{2}{3})^2 = 1$ but $x^2 \equiv 2 \pmod{9}$ is not solvable;

v) this follows from the corresponding property for the Legendre symbol since when $a \equiv b \pmod{m}$, $a \equiv b \pmod{p}$ for every prime factor $p$ of $m$;

vi) immediate from the definition;

vii) follows from the corresponding property of the Legendre symbol;
viii) write \( m = q_1 \cdots q_t \), where the primes \( q_j \) are not necessarily distinct; then, since each \( q_j - 1 \) is even and the product of 2 or more such factors is a multiple of 4, we see that
\[
m - 1 = ((q_1 - 1) + 1) \cdots ((q_t - 1) + 1) - 1
\]
\[
= 4k + (q_1 - 1) + \cdots + (q_t - 1)
\]
for suitable \( k \); thus
\[
\left( \frac{-1}{m} \right) = \left( \frac{-1}{q_1} \right) \cdots \left( \frac{-1}{q_t} \right) = (-1)^{\frac{(q_1 - 1) + \cdots + (q_t - 1)}{2}} = (-1)^{\frac{m - 1}{2}};
\]

ix) write \( m \) as in the proof of (viii) and note that, since the square of an odd number is congruent to 1 modulo 8,
\[
m^2 - 1 = ((q_1^2 - 1) + 1) \cdots ((q_t^2 - 1) + 1) - 1
\]
\[
= 64k + (q_1^2 - 1) + \cdots + (q_t^2 - 1)
\]
for suitable \( k \); thus
\[
\left( \frac{2}{m} \right) = \left( \frac{2}{q_1} \right) \cdots \left( \frac{2}{q_t} \right) = (-1)^{\frac{(q_1^2 - 1) + \cdots + (q_t^2 - 1)}{8}} = (-1)^{\frac{m^2 - 1}{8}};
\]
x) write \( m = q_1 \cdots q_{t}, \ n = p_1 \cdots p_{k} \); then
\[
\frac{m}{n} = \frac{m}{q_1} \cdots \frac{m}{q_{t}} \cdot \frac{n}{p_1} \cdots \frac{n}{p_{k}}
\]
\[
= \prod_{i=1}^{t} \frac{m}{q_i} \cdot \prod_{j=1}^{k} \frac{n}{p_j} = (-1)^{\frac{t}{2}} \left( \frac{m}{q_1} \right)^{\frac{t}{2}} \cdot \left( \frac{n}{p_1} \right)^{\frac{t}{2}}
\]
\[
= (-1)^{\frac{t}{2}} \left( \frac{q_1}{2} \right)^{\frac{t}{2}} \left( \frac{p_1}{2} \right)^{\frac{t}{2}} = (-1)^{\frac{m-1}{2}} \cdot \frac{n-1}{2}
\]

16.i) Making heavy use of #15 we have

a) \( \left( \frac{89}{107} \right) = \left( \frac{197}{89} \right) = \left( \frac{19}{89} \right) = \left( \frac{89}{19} \right) = \left( \frac{13}{19} \right) = \left( \frac{19}{13} \right) = \left( \frac{6}{13} \right) \)
\[
= \left( \frac{2}{13} \right) \left( \frac{3}{13} \right) = - \left( \frac{3}{13} \right) = - \left( \frac{13}{3} \right) = - \left( \frac{1}{3} \right) = -1 ;
\]

b) \( \left( \frac{1050}{1573} \right) = \left( \frac{2}{1573} \right) \left( \frac{525}{1573} \right) = - \left( \frac{525}{1573} \right) \)
\[
= - \left( \frac{1573}{525} \right) = - \left( \frac{-2}{525} \right) = - \left( \frac{2}{525} \right) = 1 ;
\]

c) \( (12345, 6789) \neq 1 \) so \( \left( \frac{12.3.4.5}{6789} \right) \) is not defined;

ii - a, b) since 89 = 4 \cdot 22 + 1 and 89 and 197 are prime #14 tells us that (a) and (b) are both solvable or both insolvable; by (i-a) we see (a) is not solvable so (b) is also not solvable;
c) this is solvable because 1050 is a qr of 11 and 13 and hence of all prime factors of 1573;

d) this is not solvable because 1573 is a qnr of the prime factor 5 of 1050;

e) using \# 1 (ii - 6) we see \( d = 3 = t \) so \( \frac{m}{d} = \frac{219}{3} = 73 \) and the congruence is solvable if and only if \((3, 73) = 1\) and \(x^2 \equiv 111 \equiv 38 \pmod{73}\) is solvable; but \((3, 73)\) is equal to 1, 73 is a prime and \((\frac{38}{73}) = 1\); thus the congruence in (e) is solvable;

f) again using \# 1 (ii - 6) we see \( d = 3 = t \) so \( \frac{m}{d} = \frac{219}{3} = 73 \) and the congruence is solvable if and only if \((3, 37) = 1\) and \(x^2 \equiv 219 \equiv 34 \pmod{37}\) is solvable; again, as in (e) the modulus is a prime and \((\frac{34}{37}) = 1\); thus the congruence in (f) is solvable.
(This problem shows that all possible situations may occur for pairs of congruences of the type
\[ x^2 \equiv a \pmod{6}, \quad x^2 \equiv b \pmod{4a} \];
either both are insolvable, exactly one is solvable, or both are solvable.)

17. i) By \#1 (i), \( f(x) \equiv 0 \pmod{p} \) if and only if
\( (2ax+b)^2 \equiv 0 \pmod{4ap} \); i.e., if and only if
\( (2x+1)^2 \equiv -163 \pmod{4p} \); but, making heavy use of the Jacobi symbol and \#15, we see \( \left( \frac{-163}{p} \right) = -1 \)
for all primes \( p < 41 \) so the conclusion follows;

ii) this is immediate from (i);

iii) all of the values
\[ f(-40), f(-39), \ldots, f(-1), f(0), f(1), \ldots, f(39) \]
are positive and smaller than \( 41^2 \) so all are prime.
18. i) If \( Z_o a = Z_o b \) then \( Da \equiv Db \pmod{p} \) and, therefore, \( a \equiv b \pmod{p} \); similarly for \( T_o \);

\[ i) \ T_o (T_o a) = T_o (Da^{-1}) = T_o (Da^{-2}) = D(Da^{-1})^{-1} = DD^{-1}a = \tilde{a} = a, \text{ for all } a \text{ in } A; \]

\[ ii) \ T_o T_1(a) = T_o (a^{-1}) = T_o a^{-1} = D(a^{-1})^{-1} = D\tilde{a} = Z_o a; \]

\[ iii) \ T_o x = x \text{ implies } D\tilde{x} = x \text{ which, in turn, implies } x^2 \equiv D \pmod{p}; \text{ by } \#3 (ii-a) \text{ the conclusion follows; } \]

v) Since \( T_o \) is an involution its cyclic representation, as a permutation, consists of \( \alpha_o \) cycles of length 1 and \( \frac{\varphi(p) - \alpha_o}{2} \) transpositions (cycles of length 2); therefore \( \text{sgn } T_o = (-1)^{ \frac{\varphi(p) - \alpha_o}{2} }; \)

From (iii) we find
\[ \text{sgn } Z_o = (\text{sgn } T_o)(\text{sgn } T_1) = (-1)^{ \frac{\varphi(p) - \alpha_o + \alpha_1}{2} } = (-1)^{ \frac{\alpha_o + \alpha_1}{2} }; \]
vi) this follows from \((\nu)\) since \(1\) is a qr of \(p\);

vii) by (v) and (vi), \(\text{sgn } \mathbb{Z}_0 = (-1)^{\frac{\alpha_0 + 2}{2}}\); when \(D\) is a qr of \(p\) this is \(1\) and when \(D\) is a qnr of \(p\) this is \(-1\), as we see by noting the value of \(\alpha_0\) from (iv);

viii) this follows from (vii) when we take 
\[ A = \{1, 2, \ldots, p-1\} \]

ix) taking \(A = \{-\frac{p-1}{2}, \ldots, -1, 1, 2, \ldots, \frac{p-1}{2}\}\) then \(\mathbb{Z}_1\) gives the permutation
\[ \frac{p-1}{2}, \ldots, 1, -1, -2, \ldots, -\frac{p-1}{2} \]
and clearly \(\frac{p-1}{2}\) transpositions lead back to the original order of \(A\); hence \((-\frac{1}{p}) = \text{sgn } \mathbb{Z}_1 = (-1)^{\frac{p-1}{2}}\);

taking \(A = \{1, 2, \ldots, p-1\}\) then \(\mathbb{Z}_2\) gives the permutation \(2, 4, \ldots, p-1, 1, 3, \ldots, p-2\) and the number of transpositions putting it back in the original order is \(\frac{p-1}{2} + \left(\frac{p-1}{2} - 1\right) + \cdots + 1 = \frac{(p-1)(p+1)}{2} = \frac{p^2 - 1}{8}\) so \((-\frac{2}{p}) = \text{sgn } \mathbb{Z}_2 = (-1)^{\frac{p^2 - 1}{8}}\).
19. i) Since whenever \( a \in A \) so also is \( -a \in A \), we have from \( \overline{a} < a'' \) and \( \overline{D_\alpha} > \overline{Da}'' \) the following: \( a'' < -a' \) and \( -\overline{D_\alpha}'' = -\overline{Da}'' > -\overline{D_\alpha}' = -\overline{Da}' \);

ii) \( a', a'' \) and \( -a', -a'' \) are different unless \( a' = -a'' \);

iii) \( \text{sign } Z_0 = (-1)^\alpha \) where \( \alpha \) is the number of inversions of the form \( -a, a \); for exactly such inversions \( a \in A^+ \) and \( \overline{Da} = -a \in A^- \);

iv) take \( D = q \) and \( D = p \) respectively in the above and use (iii) as well as \( *18 \) (vii);

v) if \( qx - py = 0 \) then \( qx = py \) so \( p \) would divide \( x \), which is not possible since \( 1 \leq x \leq \frac{p-1}{2} \); thus, since \( qx - py \neq 0 \) the four inequalities exhaust all possibilities;
vi) the mapping \( x, y \leftrightarrow \frac{p+1}{2} - x, \frac{q+1}{2} - y \) proves the 1st assertion; the 2nd assertion follows from (iv);

vii) by (vi), \( n + v \equiv \text{total number of pairs } x, y \text{ in (v)} \equiv \frac{p-1}{2} \cdot \frac{q-1}{2} \pmod{2} \); now use (iv).
Exponents, Primitive Roots, Power Residues — Solutions

1. i) Let \( s-t = q\varphi(a)+r, \quad 0 \leq r < \varphi(a) \); then
\[
a^s = a^{t+q\varphi(a)+r} = a^t(a^{\varphi(a)})^q a^r \equiv a^t a^r \equiv a^r \pmod{m}.
\]
since \((a^t, m) = 1\) this implies \(a^r \equiv 1 \pmod{m}\); if \(r \neq 0\) then \(\varphi(a)\) would not be the exponent of \(a\); consequently \(r = 0\) and \(\varphi(a)\) divides \(s-t\);

ii) (a) and (b) follow from (i) by, respectively, putting \(t = 0\) and \(s = \varphi(m), t = 0\); in (c) the given quantities are clearly solutions of the stated congruence; if \(a^i \equiv a^j \pmod{m}\) then by (i), \(\varphi(a) | i-j\); but this may not happen for \(i, j\) among \(1, 2, \ldots, \varphi(a)\) unless \(i = j\);

iii) \((a^x)^r \equiv 1 \pmod{m}\) if and only if \(k \equiv 0 \pmod{\varphi(a)}\); this last congruence is equivalent to the one obtained by dividing all parts by \((k, \varphi(a))\) and then dividing
all parts, except the modulus, by the new coefficient of \( t \), which is prime to the modulus and hence results in an equivalent congruence; the result is \( t \equiv \frac{P(a)}{(a, P(a))} \); since the least possible positive value for \( t \) is clearly the modulus in this last congruence we have the desired conclusion;

w-a) if \( t \nmid \varphi(m) \) then \( t \) can be the exponent mod \( m \) of no integer since all such exponents must divide \( \varphi(m) \), as seen in (ii-6);

b) every number prime to \( p \) has some exponent which is a divisor of \( \varphi(m) \); since no number has more than one exponent the sum on the left is clearly just the number of integers mod \( m \), prime to \( m \), i.e. \( \varphi(m) \);

c) let \( P(a) = t \); then \( a, a^2, \ldots, a^t \) are prime to \( m \) and their exponents are given by (iii); the number of \( k \) in (iii) for which \( P(a^k) = P(a) = t \) is just the number of \( k \) for which \( (k, P(a)) = 1 \), i.e.
\( \varphi(P(a)) = \varphi(t) \); thus \( \varphi(t) \) is at least as large as \( \varphi(t) \);

v-a) in this case, when \( P_p(a) = t \), then \( a, a^2, \ldots, a^t \) are all the solutions of \( x^t \equiv 1 \pmod{p} \); hence by (iii) exactly \( \varphi(t) \) of them have exponent \( t \);

b) by \( (\varpi - 6, c) \) and \( \text{viii} \neq \varpi \) we have

\[
p^{-1} = \prod_{p-1} \varphi_p(t) \leq \prod_{p-1} \varphi(t) = p^{-1} ;
\]
thus \( \prod_{p-1} \varphi_p(t) = \prod_{p-1} \varphi(t) \); this with the inequality in \( (\varpi - c) \) yields the desired conclusion;

v) immediate from (v-b) when one takes \( t = p - 1 \).

2. i) \( \varphi(p) = p - 1 \), \( p - 1 | P_p \alpha(q) \), and \( P_p \alpha(q) | q^{(p^\alpha)} = p^{\alpha-1}(p - 1) \); thus \( P_p \alpha(q) = p^\beta(p - 1) \) for some \( \beta \), \( 0 \leq \beta \leq \alpha - 1 \); since \( q^{\varphi(p^\alpha)} \equiv 1 \pmod{p^\alpha} \) this means \( \beta = \alpha - 1 \) and the conclusion follows;
ii) since \((q+p)^{p-1} \equiv q^{p-2}p \equiv 0 \pmod{p^2}\)
we see that not both \((q+p)^{p-1}\) and \(q^{p-2}\) are congruent to 1 \((\pmod{p^2})\); the result now follows from (i) since we know \(q\) and \(q+p\)
are primitive roots of \(p\);

iii) using \(\nu \equiv 24\) it is easy to see \((j \geq 2)\) that
the highest power of \(p\) in \(\binom{p^j}{j}\) is \(\geq j+2-j\); thus, if \(q\) is a primitive root of \(p^2\) then \(q^{p-1} = 1+qp\),
where \(p\nmid q\); hence \(q^{\phi(p^2)/p} = (q^{p-1})^{p^{\alpha-2}}\)
\[= (1+qp)^{p^{\alpha-2}} \equiv 1 + qp^{\alpha-1} \pmod{p^\alpha};\]
the result now follows from (i);

iv) \(a^t \equiv 1 \pmod{2p^n}\) implies \(a^t \equiv 1 \pmod{p^n}\)
and \(a\) is odd; if \(a\) is a primitive root of \(p^\alpha\) then the largest \(t\) could be is \(\phi(p^\alpha) = \phi(2p^n)\);
this completes the proof;

v) this follows from (ii), (iii), (iv), and \(\#s(vi)\);
vi) for all other numbers the function \( \chi(m) \), introduced in \( x=9 \) is smaller than \( \Phi(m) \) and the conclusion follows then from that problem part (i); for powers of 2 larger than 2 the conclusion also follows from \( x=8(6) \).

3. i) If \( q \) is a primitive root of \( p^{a+1} \) but not of \( p^a \) then for some \( t \), \( 0 < t < \Phi(p^a) \), 
\( q^t \equiv 1 \pmod{p^a} \); but then \( q^t = 1 + sp^a \) and, therefore, \( q^{2p} = (1 + sp^a)^2 \equiv 1 \pmod{p^{a+1}} \); 
since \( tp < p \) \( \Phi(p^a) = p^a(p-1) = \Phi(p^{a+1}) \) this contradicts \( q \) being a primitive root of \( p^{a+1} \);

ii) the numbers in question are all primitive roots of \( p \) and, defining \( q \) by \( q^{p-1} = 1 + qp \), we see that \( ((1+sp)q)^{p^{a+1}} \equiv (1+qp)(1-qp) \pmod{p^2} \); except when \( s \equiv q \pmod{p} \) this right hand side is not congruent to 1 \( \pmod{p^2} \); consequently by *2(i) the conclusion follows;
iii) by $\#1 (vi)$ there are $\varphi(p-1)$ primitive roots of $p$; by (ii), to each of these there are $p-1$ primitive roots of $p^2$; hence the number of primitive roots of $p^2$ is

$$(p-1)\varphi(p-1) = \varphi(p^{p-1}) = \varphi(\varphi(p^2)).$$

iv) by (i) and $\#2 (iii)$ if $q$ is a primitive root of $p^\alpha$, $\alpha \geq 2$, then $q$ is a primitive root of $p^2$, and, thus, a primitive root of $p^{\alpha+1}$; but then $q, q + p^\alpha, \ldots, q + (p-1)p^\alpha$ are all primitive roots of $p^{\alpha+1}$ and exhaust those congruent to $q$

(again by (i));

v) by (iii) there are $\varphi(\varphi(p^2))$ primitive roots of $p^2$ and by iterated use of (iv) there are then $p^{\alpha-2}\varphi(\varphi(p^2))$ primitive roots of $p^\alpha$; but $\varphi(\varphi(p^\alpha)) = \varphi(p^{\alpha-1}(p-1)) = \varphi(p^{\alpha-1})\varphi(p-1) = p^{\alpha-2}(p-1)\varphi(p-1) = p^{\alpha-2}\varphi(\varphi(p^2))$;
vi) this follows from (v), *2 (w), and direct checking for 2 and 4.

4. i) By *(i)**(iii)**, \( P(a^u) = \frac{P(a)}{(u, P(a))} = \frac{uv}{u, uv} = \frac{uv}{u} = v; \)

ii) let \( P(a) = u, P(b) = v, P(ab) = w; \) then \( 1 \equiv (ab)^w v \equiv (ab)^w u \equiv b^w u \equiv (ab)^w v \equiv a^w v \pmod{m}; \)
hence each of \( u \) and \( v \) divides \( w \) which, in turn, divides \( uv; \)

(iii) with \( m = 7, a = 3, b = 5 \) we have \( P(3, 5) = 1 \) but \([P(3), P(5)] = [6, 6] = 6; \)

iv) let \( P(a) = u, P(b) = v \) and choose \( u_0, v_0 \)
such that \( u_0 | u, v_0 | v, (u_0, v_0) = 1, u_0 v_0 = [u, v] \)
(this can be done for example by using the prime factorizations of \( u \) and \( v \)); put \( c = a^{\frac{u_0}{v_0}} b^{\frac{v_0}{u_0}} \);
then, using *(i)**(iii)**,
\[
P(a^{\frac{u_0}{v_0}}) = \frac{P(a)}{(\frac{u_0}{v_0}, P(a))} = \frac{u}{(\frac{u_0}{v_0}, u)} = u_0,
\]
and similarly, \( P \left( b^{v_0} \right) = v_0; \) thus, by (ii),
\[
P(a^{v_0}, b^{v_0}) = u_0v_0 = [u, v];
\]

v) let \( P \) be the largest exponent and suppose
\((a, m) = 1; \) then, by (\( \hat{w} \)), there is an integer \( c \) such
that \( P(c) = [P, P(a)] \); but this means
\[
P \leq P(c) \leq P \) so \( P = [P, P(a)] \) and \( P(a) | P; \)

vi) let \( P \) be the largest exponent of the
prime \( p \); then, using (v), \( x^p \equiv 1 \pmod{p} \) has
\( \Phi(p) \) solutions so \( \Phi(p) \leq P \); but \( P | \Phi(p) \) so
\( P \leq \Phi(p) \); this means \( P = \Phi(p) \) and \( p \) has a
primitive root;

vii) if \( g \) is a primitive root of \( p \) then \( g^t \) is
also for all \( t \) satisfying \( (t, p-1) = 1 \) since, by
\[
\Phi \left( \Phi(p) \right) = \frac{\varphi(p)}{(t, \varphi(p))} = \frac{p-1}{(t, p-1)} = p-1.
\]
5. i) If \( a \) has order \( u \) and \( b \) has order \( v \) choose \( u_0, v_0, c \) as in the proof of \#4 (\( \$w \)) ; then the order of \( c \) is \([u, v] \) ;

ii) the proof is like that of \#4 (\( v \)) ;

iii) if the group \( G \) is of order \( q \) and the maximal element in \( A_G \) is \( P \) then \( P \leq q \) and \( x^p = 1 \) has \( q \) solutions ; but in a field the equation \( x^p = 1 \) has at most \( P \) solutions ; thus \( P = q \) and the desired result follows ;

iv) immediate from (iii) ;

v) a cyclic group of \( p - 1 \) elements has \( \varphi (p - 1) \) generators ; similarly we can deduce \#3 (\( v \)) from (iv) .
6. i) Let \( q \) be a primitive root of \( p \); if \( x^n \equiv a \pmod{p} \) and \( x \equiv q^s \pmod{p} \) then
\[
a^{\frac{p-1}{d}} \equiv 1 \pmod{p};
\]
on the other hand, if \( a^{\frac{p-1}{d}} \equiv 1 \pmod{p} \) and \( a \equiv q^t \pmod{p} \) then \( q^t \cdot a^{\frac{p-1}{d}} \equiv 1 \pmod{p} \) so \( d \mid t \) and \( t \equiv ns \pmod{p-1} \) is solvable for \( s \) yielding \( q^t \equiv q^{ns} \equiv a \pmod{p} \), so \( x^n \equiv a \pmod{p} \) has \( x=q^s \) as a solution;

ii) this follows from (i) by taking \( n=d \);

iii) since the number of \( d \)-th power residues modulo \( p \) cannot exceed \( \frac{p-1}{d} \), see (ii),
the conclusion must be true;

iv-a) let \( t \) be the exponent of \( B_i \) modulo \( p \); then, since \( B_i^{p_i} = A_i^{p-1} \equiv 1 \pmod{p} \), we know
t \mid p_i^{\alpha_i}; \text{ but, since } A_i^{\frac{p-1}{p_i}} \not\equiv 1 \pmod{p} \text{ we know that } t < p_i^{\alpha_i} \text{ is false; thus } t = p_i^{\alpha_i};

b) \text{ since for } i \neq j, (P(B_i), P(B_j)) = 1 \text{ we may use the finite extension of } \#4(ii) \text{ to obtain}

\[ P(B_1 \cdots B_k) = P(B_1) \cdots P(B_k) = p_1^{\alpha_1} \cdots p_k^{\alpha_k} = p - 1. \]

7. i) We first find $A_1, A_2, A_3$ so that

\[ A_1^{42} \not\equiv 1, A_2^{42} \not\equiv 1, A_3^{42} \not\equiv 1 \pmod{43}; \]

where the 2, 3, 7 are the prime factors of 42, 42 = 2 \cdot 3 \cdot 7; it is easy to see we may take

\[ A_1 = 2, A_2 = 7, A_3 = 3 \]

and that $2^{21} \equiv -1, 7^{14} \equiv 6, 3^6 \equiv -2 \pmod{43}$; since all $\alpha_i \equiv 1$ we find

\[ B_1 = 2^{21}, B_2 = 7^{14}, B_3 = 3^6 \text{ so } B_1B_2B_3 \equiv 12 \pmod{43}; \]

therefore 12 is a primitive root modulo 43;
ii) using \(12\) we have the table:

<table>
<thead>
<tr>
<th>power of 12</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>no. (\equiv) to (mod 43)</td>
<td>(12)</td>
<td>15</td>
<td>8</td>
<td>10</td>
<td>(-9)</td>
<td>21</td>
</tr>
<tr>
<td>exponent</td>
<td>42</td>
<td>21</td>
<td>14</td>
<td>21</td>
<td>42</td>
<td>7</td>
</tr>
</tbody>
</table>

\[
\begin{array}{cccccccccccc}
7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \\
-6 & 14 & -4 & -5 & \text{–}17 & 11 & \text{–}3 & -7 & 2 & -19 & \text{–}13 & -27 \\
6 & 21 & 14 & 21 & 42 & 7 & 42 & 21 & 14 & 21 & 42 & 21 \\
\text{–}20 & -18 & -1 & -12 & \text{–}15 & -8 & \text{–}10 & 9 & -21 & 6 & \text{–}14 & 4 \\
42 & 21 & 2 & 21 & 42 & 7 & 42 & 21 & 14 & 3 & 42 & 7 \\
31 & 32 & 33 & 34 & 35 & 36 & 37 & 38 & 39 & 40 & 41 & 42 \\
5 & 17 & -11 & -3 & 7 & -2 & \text{–}19 & 13 & -16 & -20 & \text{–}18 & 1 \\
42 & 21 & 14 & 21 & 6 & 7 & 42 & 21 & 14 & 21 & 42 & 1 \\
\end{array}
\]

we have circled the primitive roots; the least is 3 and the least absolute is 3; for an easier method to carry out these computations, see Ch. 8 of Uspensky & Heaslet, Elementary Number Theory.
8. i) When \((3, p-1) = 1\) all integers \(a\), prime to \(p\), are cubic residues of \(p\) (see \(\#6(i)\)); thus since 
\((3, 4) = (3, 10) = 1\) all integers are cubic residues modulo 5 and 11;

ii) this follows as in the proof of (i) since 
\((5, 6) = 1\);

iii) when \(n\) is odd, \((n, 4) = (n, 16) = 1\); thus the conclusion follows from \(\#6(i)\);

iv) if all \(a\), \(p \nmid a\), are \(n^{\#5}\) power residues modulo \(p\) then \((n, p-1) = 1\) since otherwise no such \(a\) would have exponent \(p-1\) and this contradicts the existence of primitive roots for all odd primes; thus for all odd \(n\), \((n, p-1) = 1\); this means \(p-1\) must be a power of 2 and, hence, \(p\) is a Fermat prime; the other direction is clear since when \(n\) is odd and \(p\) is a Fermat prime we always have \((n, p-1) = 1\);
v) by $x_{iv} \equiv 17 (vi)$ given $n > 1$ there are infinitely many primes $p$ of the form $nk + 1$; for each of these $(n, p - 1) = n$ and therefore if all integers were $n^{th}$ power residues then such $p$ would have no primitive roots contrary to fact.

9. If $p - 1 | n$ then $j^n \equiv 1 (\mod p)$ so the left side is congruent to $p - 1$ and hence to $-1 \mod p$; otherwise let $q$ be a primitive root modulo $p$ and note that $1, 2, \ldots, p - 1$ are congruent, in some order, to $q, q^2, \ldots, q^{p - 1}$; hence

$$1^n + 2^n + \ldots + (p - 1)^n \equiv q^n + q^{2n} + \ldots + q^{(p - 1)n} (\mod p)$$

now, since $p - 1 \nmid n$, $1 - q^n \not\equiv 0 (\mod p)$ so there is an $x_0$ such that $(1 - q^n)x_0 \equiv 1 (\mod p)$ and $x_0 \not\equiv 0 (\mod p)$; now

$$1^n + \ldots + (p - 1)^n \equiv q^n + \ldots + q^{(p - 1)n}$$

$$\equiv x_0(1 - q^n)(q^n + \ldots + q^{(p - 1)n}) \equiv x_0q^n(1 - q^{(p - 1)n})$$

$$\equiv 0 (\mod p).$$
10. If \( a^t \equiv 1 \pmod{a^{n-1}} \) then \( t \geq n \); since \( a^n \equiv 1 \pmod{a^{n-1}} \) we see that \( n \) is the exponent of \( a \pmod{a^{n-1}} \); the conclusion now follows from \#1 (ii-5).

11. Let \( q \) be a primitive root modulo \( p \); then the product in question is just, using \#16,
\[
\prod_{t \equiv 1 \pmod{p-1}} q^t = q^{\frac{p-1}{2} \varphi(p-1)} \equiv 1 \pmod{p},
\]
since \( \varphi(p-1) \) is even and \( q^{p-2} \equiv 1 \pmod{p} \).

12. If \( q \) is a primitive root modulo \( m, m > 2 \), then
\[
\prod_{n=1 \atop (n,m)=1}^m q^t \equiv q^{\left(\varphi(m)+1\right) \frac{\varphi(m)}{2}} \equiv q^{\frac{\varphi(m)}{2}} \pmod{m};
\]
since \( q^{\frac{\varphi(m)}{2}+1} \equiv q^{\frac{\varphi(m)}{2}} \equiv 0 \pmod{m} \) and \( q^{\frac{\varphi(m)}{2}-1} \not\equiv 0 \pmod{m} \) we have the desired conclusion; on the other hand when \( m \) has no primitive root we may follow the lines of the proof of \#12 except that now it is not true that \( x^2 \equiv 1 \pmod{m} \) has only the two solutions \( 1 \) and \( m-1 \) since
the number of solutions is given in XVII \#3 (vi) and is
\[ 2^k \text{ if } 4 \mid m; \quad 2^{k+1} \text{ if } 4 \mid m, 8 \mid m; \quad 2^{k+2} \text{ if } 8 \mid m, \]
where \( k \) is the number of distinct odd prime factors of \( m \); if \( n \) has no primitive root then, by \#2(vi), either
\[ k = 0, \quad 8 \mid m \text{ or } k = 1, 4 \mid m \text{ or } k \geq 2; \]
in all of these cases the number of solutions is divisible by 4; noting that the solutions of \( x^2 \equiv 1 \pmod{m} \) fall into pairs \( x, -x \) with a product \(-x^2 \equiv 1 \pmod{m}\) we see that the product of all solutions is \((-1)^s\), where \( s \) is the number of pairs; but \( s \) is even since the total number of solutions of \( x^2 \equiv 1 \pmod{m} \) is divisible by 4; the proof is now finished in an identical way to that of IX \#12. (It should be noted that the method of the 2nd half of the proof to this problem is also applicable to the 1st half—namely, to the case where \( m \) does have a primitive root.)
13. (A) First we show that \( Q \) as defined is < \( x \); 

Case 1. \( t \) even; if \( 2^{\frac{t}{2}} \equiv -1 \pmod{2x+1} \) then \( Q = \frac{1}{2} t - 1 < \frac{1}{2} t \leq \frac{1}{2} \varphi(2x+1) \leq \frac{1}{2}(2x) = x \); if \( 2^{\frac{t}{2}} \not\equiv -1 \pmod{2x+1} \) then \( 2x+1 \) is not a prime, for if it were \((2^{\frac{t}{2}} + 1)(2^{\frac{t}{2}} - 1) = 2^t - 1 \equiv 0 \pmod{2x+1} \) and \( 2^{\frac{t}{2}} \equiv 1 \pmod{2x+1} \); thus \( t \mid \varphi(2x+1) < 2x \) so \( Q = t - 1 < x \); 

Case 2. \( t \) odd; here \( t \leq \frac{1}{2} \varphi(2x+1) \leq x \) so \( Q = t - 1 < x \); 

(B) suppose now that \( t \) is even and \( 2^{t/2} \equiv -1 \pmod{2x+1} \); then \( 2^{t/2} = -1 + q \pmod{2x+1} \) for some odd \( q \), say \( q = 2s+1 \) (for \( x = 1 \) the assertion in the problem is obvious); then \( 2^{2\alpha} = 2^{(t/2)-1} = \frac{-1 + (2s+1)(2x+1)}{2} = (2s+1)x + s \) is in the progression; further, if \( 2^{2\alpha} = (2s+1)x + s \) for some \( s \) and if \( \alpha \) is as small as possible we have \( 2^{\alpha+1} \equiv 2x \equiv -1 \pmod{2x+1} \) so \( 2^{2\alpha + 2} \equiv 1 \pmod{2x+1} \); thus \( \alpha \leq \frac{1}{2} t - 1 \) and \( t \mid 2\alpha + 2 \) so \( \alpha = \frac{1}{2} t - 1 \) and \( 2^{\alpha} \) is the smallest power of 2 in the progression;
(C) suppose finally that \( t \) does not satisfy the conditions of (B); then \( 2^{\alpha+1} = 2^t = 1 + q(2^x + 1) \) for some odd \( q \), say \( q = 2s + 1 \); thus
\[
2^\alpha - 1 = -1 + \frac{1 + (2s+1)(2x+1)}{2} = (2s+1)x + s
\]
is in the progression; further, if \( 2^{\alpha+1} = (2s+1)x + s \) and \( \alpha \) is as small as possible then
\[
2^{\alpha+1} = 2 + 2x \equiv 1 \pmod{2x+1};
\]
thus \( \alpha \leq t-1 \) and \( t \mid \alpha+1 \) so \( \alpha = t-1 \).

14. If \( 2^\alpha \) were in the sequence then \( Q > 3 \) since 1, 2, 4, 8 are not in the sequence; if \( 5+7x = 2^\alpha \), \( Q > 3 \), then \( x \) is odd, say \( x = 2x_1 + 1 \), which yields \( 6+7x_1 = 2^{\alpha-1} \) and \( x_1 \) is even, say \( x_1 = 2x_2 \), which yields \( 3+7x_2 = 2^{\alpha-2} \) and \( x_2 \) is odd, say \( x_2 = 2x_3 + 1 \), which yields \( 5+7x_3 = 2^{\alpha-3} \); thus if \( 2^\alpha \) \( Q > 3 \), is in the sequence then \( 2^{\alpha-3} \) is also in the sequence; iteration leads to a contradiction; if \( 5+7x = 2^\alpha - 1 \) then \( Q > 2 \), since 0, 1, 3 are not in the sequence; from \( 5+7x = 2^\alpha - 1 \) we
see x is even, say x = 2x₂, which yields
3 + 7x₁ = 2^{a-1} where x₁ is odd, say x₁ = 2x₂ + 1,
which yields 5 + 7x₂ = 2^{a-2}, which we know is
impossible by the first part of the argument.

15. i) The identity is clear as is the congruence
modulo 2^{n+2}; noting that 5^{2^j} + 1 ⊖ 2 (mod 4)
we see that none of the factors 5^{2^j} + 1 are
divisible by 4 and the incongruence assertion
follows;

ii) this is an immediate consequence of (i);

iii) clearly 1, 5, 5², ..., 5^{a-2} and -1, -5, -5², ..., -5^{a-2}
are pairwise incongruent modulo 2^a, among
themselves; further, each of the 1st
group of numbers is congruent modulo 8 to either
1 or 5, while each of the 2nd group of numbers
is congruent modulo 8 to either 3 or 7;
thus no member of the 1st group is congruent to a member of the 2nd group modulo 8, and, therefore, since $\alpha > 2$, modulo $2^\alpha$. 
Special Primes and the Lucas-Lehmer Theorem - Solutions

1. i) \( (\frac{3}{F_n}) = (-1)^{\frac{2^{2^n-1} - 1}{2}} \cdot \left( \frac{F_n}{3} \right) = \left( \frac{F_n}{3} \right) = \left( \frac{2}{3} \right) = (-1)^{\frac{3^2 - 1}{8}} = -1 \), where we have used the fact that 
   \( F_n \equiv (-1)^{2^n} + 1 \equiv 2 \pmod{3} \);

ii) by hypothesis \( 3^{F_n - 1} \equiv 1 \pmod{F_n} \) so 
   \( p_{F_n}(3) \mid F_n - 1 \) and this implies \( p_{F_n}(3) \) is a power 
   of 2; but this power cannot be smaller than 
   \( F_n - 1 \) itself since \( 3^{F_n - 1} \not\equiv 1 \pmod{F_n} \); 
   consequently \( p_{F_n}(3) = F_n - 1 \); finally, 
   \( F_n - 1 = p_{F_n}(3) \leq \varphi(F_n) \leq F_n - 1 \) 
   so \( \varphi(F_n) = F_n - 1 \) and \( F_n \) must be a prime;

iii) when \( F_n \) is prime then, by (ii), \( (\frac{3}{F_n}) = -1 \) 
   and, by Euler's criterion, see xvi*5(ii), this 
   implies \( 3^{\frac{F_n - 1}{2}} \equiv -1 \pmod{p} \); the opposite implication 
   is precisely the statement in (iii).
2. i) \( 2^n \equiv -1 \pmod{p} \) so \( 2^{n+1} \equiv 1 \pmod{p} \) and, therefore, \( p \mid 2^{n+1} \); if \( p \mid 2^m, m < n+1 \), then \( 2^n \equiv 1 \pmod{p} \) contrary to fact;

ii) since \( p \mid \varphi(p) \) we know \( 2^{n+1} \mid p - 1 \); hence \( p^2 - 1 = (p+1)(p-1) \) is divisible by at least the \( 4 \times 6 \) power of 2 (recall that \( n > 1 \) and \( p \) is odd); therefore \( \left( \frac{2}{p} \right) = (-1)^{p^2-1} \equiv 1 \pmod{p} \) and the result follows;

iii) since, by (ii), \( \left( \frac{2}{p} \right) = 1 \) Euler's criterion tells us \( 2^{p-1} \equiv 1 \pmod{p} \); thus \( p \mid 2^{n+1} \) divides \( p^{\frac{p-1}{2}} \);

iv) from (i)-(iii);

v) since the \( F_n \) are pairwise relatively prime, see III*9 (vii-b), prime factors of different \( F_n \) are different; now let \( p_1, p_2, p_3, \ldots \) be a sequence
of prime numbers such that \( p_n \mid F_n \); then, by (iv), \( p_n \) is in the stated sequence for all values of \( n \geq k - 2 \).

3. i) \( F_5 = 4, 294,967,297 \) with possible prime divisors of the form \( 1 + 2^7 \cdot t \), \( 1 \leq t \leq 2^{25} \); calculation shows \( 1 + 2^7 \cdot t \) is not prime for \( t = 1, 3, 4 \) but is prime for \( t = 2, 5 \); for \( t = 2 \) the resulting prime 257 does not divide \( F_5 \) while for \( t = 5 \) the resulting prime 641 does divide \( F_5 \) with quotient 6,700,417;

(the total calculating time here was \( \leq 10 \) minutes;)

ii) (we follow Sierpinski [1964])

compute \( r_0 \) where \( r_0 \equiv 3^2 \pmod{F_7} \);

now compute \( r_1, r_2, \ldots, r_{120} \) successively,

where \( r_{j-1}^2 \equiv r_j \pmod{F_7} \); then, since

\[
3^{F_{121} - 1} = 3^{2^{127}} \equiv r_{120} \not\equiv 1 \pmod{F_7},
\]

we see that \( F_7 \) is not prime.
4. i) If $n = ab$, $a > 1$, $b > 1$ then $2^n - 1 | 2^{ab} - 1$; 

ii-a) $\frac{q^2 - 1}{q} = \left(-1\right)^{\frac{p(p+1)}{2}} = 1$;

b) If $q | 2^p + 1$ then $2^p = 2^{q^2 - 1} \equiv -1 \pmod{q}$, which says $\left(\frac{2}{q}\right) = -1$ in contradiction to (a);

c) Since $2^{q^2 - 1} + 1 = (2^{q^2 - 1} + 1)(2^{q^2 - 1} - 1)$

$= (2^p + 1)(2^p - 1) \equiv 0 \pmod{q}$

and since, by (b), $q \nmid 2^p + 1$, $q$ must divide $M_p = 2^p - 1$;

iii) these are all immediate consequences of (ii-c);

iv) each of the examples in (iii) is a counter-example to the converse of (i).

5. i) $U_1 = 1$, $V_1 = 2$; suppose now the assertions are correct for $n$; then $U_{n+1} =$

$$\frac{1}{2\sqrt{3}} \left\{ (1+\sqrt{3})^n(1+\sqrt{3}) - (1-\sqrt{3})^n(1-\sqrt{3}) \right\} =
\frac{1}{2\sqrt{3}} \left\{ (1+\sqrt{3})^n - (1-\sqrt{3})^n + \sqrt{3} V_n \right\} = U_n + \frac{1}{2} V_n,$$
\[ \nu_{n+1} = (1 + \sqrt{3})^n (1 + \sqrt{3}) + (1 - \sqrt{3})^n (1 - \sqrt{3})^2 \]
\[ = (1 + \sqrt{3})^n + (1 - \sqrt{3})^n + \sqrt{3} (1 + \sqrt{3})^n (1 - \sqrt{3})^n \]
\[ = \nu_n + 6 \nu_n; \]
the assertions now follow for \( n+1; \)

\( \text{ii-a)} \) multiply out the right side and cancel terms;

\( \text{b-e)} \) similar to (a);

\( \text{f)} \) put \( m = n \) in (c) and use (e);

\[ \text{iii-a)} \quad U_p = \frac{1}{2} \sum_{j=0}^{p-1} (p_j) \sqrt{3}^j - \frac{p}{2} \sum_{j=0}^{p-1} (p_j) (-1)^j \sqrt{3}^j \]
\[ = \sum_{j\text{ odd}}^{p-1} (p_j) \sqrt{3}^{j-1} \equiv 3^{\frac{p-1}{2}} \equiv (\frac{3}{p}) \pmod{p}; \]

\( \text{b)} \) similar to (a);

\( \text{c)} \) put \( n = p \) in the expression for \( \nu_{n+1} \) in (i) and put \( m = 1, n = p-1 \) into (\text{ii-b)} \) to obtain

\[ 2U_{p+1} = 2U_p + \nu_p, \quad 4U_{p-1} = -2U_p + \nu_p; \]

multiply these equations to obtain

\[ 8U_{p+1}U_{p-1} = -4U_p^2 + \nu_p^2 \equiv -4 + 4 \equiv 0 \pmod{p}, \]
where we used (a) and (b) at the 2nd last congruence;
\[ \hat{w} - a \] by \((\hat{u} - a)\); 
\[ b \] by \((\hat{u} - b)\); 
\[ c - 1 \] by \((\hat{u} - c)\);

2) if \(n = q_{\omega_p} + r, 0 \leq r < \omega_p\), then, by (a) and (b), if \(r \neq 0\) then \(r = n - q_{\omega_p}\) is in \(s_p\); but this contradicts the minimality of \(\omega_p\); hence \(r = 0\) and, therefore, \(\omega_p \mid n\);

\[ v - a \] from \((\hat{u} - c)\) with \(m = 2^p - 1, n = 1\) we have, using \((\hat{u} - a, b)\), 
\[ 2V_{2^p} = 2V_{2^{p-1}} + 12U_{2^{p-1}} \equiv 4 + 12 \left(\frac{3}{2^{p-1}}\right) \pmod{2^p - 1}; \]
now \(2^5 \equiv 8 \pmod{12}\) and, therefore, as we see by induction, all odd integers \(s\), larger than 3, satisfy \(2^s \equiv 8 \pmod{12}\); hence for such \(s\), \(2^{s-1} \equiv 5 \pmod{12}\), and, for those which are prime, we have, by \(xvii\) 
\[ *11(\hat{u}), \left(\frac{3}{2^{p-1}}\right) = -1\]; consequently \(\left(\frac{3}{2^{p-1}}\right) = -1\) and
\[ 2V_{2^p} \equiv - 8 \pmod{2^p - 1}; \]

6) this follows by setting \(n = 2^{p-1}\) in \((\hat{u} - e)\);
c) Immediate from (b) and (a);

d) Immediate from (c) since
\[ 2^{-\frac{M_p}{2^{q-1}}} \equiv \left( \frac{2}{M_p} \right) \equiv 1 \pmod{M_p}; \]

vi-a) since \( M_q = 2^q - 1 \equiv (-1)^q - 1 \equiv -2 \pmod{3}, \)
we see \( p \neq 3; \)

b) From (ii-d) we see \( U_{2q} = U_{2q-1} \cdot V_{2q-1} \) so from \( p | V_{2q-1} \) we conclude \( p | U_{2q}; \)

c) By (b), \( 2^q \) is in \( S_p \) so, by (i\( \ast \)-c-2), \( \omega_p | 2^q; \)

d) If \( \omega_p | 2^{q-1} \) then, by (i\( \ast \)-c-2), \( 2^{q-1} \) is in \( S_p \)
so \( p | U_{2q-1} \) and, therefore, by (iii-f) we conclude \( p | (2^q)^{-1} + 2 \), contrary to fact; 

e) Immediate from (c) and (d);

f) From (i\( \ast \)-c-1) we know \( \omega_p = 2^q \leq p + 1; \)
thus \( M_q = 2^q - 1 \leq p; \) but \( p \leq M_q \) so \( M_q = p; \)

vi\( i\)) \( V_2 = 8 = 2^{2^{3-1}} \cdot 4 \) so put \( s_1 = 4; \) suppose \( s_1, \ldots, s_k \) have been correctly chosen; then,
using \((\nu-c)\),

\[
V_{2k+1} = V_{2k} + (-2)^{2k+1} = 2^{2k} \cdot s_k^2 + (-2)^{2k+1} = 2^{2k} (s_k^2 - 2);
\]

so we put \(s_{k+1} = s_k^2 - 2\);

\(\text{viii}) \) if \(M_p\) is prime then, by \((v-d)\), \(M_p \mid V_{2p-1}\) and, therefore, by \((v\nu)\), \(M_p \mid s_{p-1}\); on the other hand, any odd prime divisor of \(M_p\) must, when \(M_p\) divides \(V_{2p-1}\), which is true when \(M_p \mid s_{p-1}\), by \((vii)\), equal \(M_p\); i.e. \(M_p\) itself a prime;

\(\text{iix})\) we may note that all \(s_k\) are even so we may suppress a factor of 2 in each term; this yields

\[
t_1 = \frac{s_1}{2} = 2,
\]

\[
t_{k+1} = \frac{s_{k+1}}{2} = 2 \left(\frac{s_k}{2}\right)^2 - 1 = 2 \cdot t_k^2 - 1.
\]
xx Pell Equation - Solutions

1. (a) Since $ay$, for $y$ an integer, is never an integer it must lie between two consecutive integers; let $x$ be the larger of these integers;

(b) for each of the $m+1$ values of $y$, $0 \leq y \leq m$, we select $x$ as in (a); the $m+1$ resulting numbers must contain a pair within $\frac{1}{m}$ of each other and their difference yields the desired result;

c) this follows from (b) since $\frac{1}{m} \leq \frac{1}{y}$;

\[ n^{-a}) \quad |x+y\sqrt{D}| = |x-y\sqrt{D} + 2y\sqrt{D}| \]
\[ \leq |x-y\sqrt{D}| + 2y\sqrt{D} < \frac{x}{y} + 2y\sqrt{D}; \]

multiplying this inequality by $|x-y\sqrt{D}| < \frac{1}{y}$ yields $|x^2 - Dy^2| < \frac{1}{y^2} + 2\sqrt{D} \leq 1 + 2\sqrt{D}$;

(b) since infinitely many pairs $x,y$ lead to $|x^2 - Dy^2| \leq 1 + 2\sqrt{D}$ there must be some infinite number of $x^2 - Dy^2$ having the same integral value;
c) modulo \( k \) the integers \( x, y \) are all in \( k^2 \) pairs of residue classes; since there are infinitely many such pairs \( x, y \) some two are in the same pair of classes;

\( d - 1 \) \( x_3 = x_1 x_2 - D y_1 y_2 \equiv x_1^2 - Dy_1^2 \equiv k \equiv 0 \pmod{k} \); 
\[ y_3 = x_2 y_1 - x_1 y_2 \equiv x_1 y_1 - x_1 y_1 \equiv 0 \pmod{k} ; \]

2) if \( y_3 = 0 \) then \( x_2 = \frac{x_1 y_2}{y_1} \) so
\[ k = x_2^2 - Dy_2^2 = \frac{y_2^2}{y_1^2} (x_1^2 - Dy_1^2) = (\frac{y_1}{y_1})^2 k \]
and, therefore, \( y_1 = y_2 \); but then \( x_1 = x_2 \) and the two pairs are not distinct;

3) \( x_3^2 - Dy_3^2 = (x_1^2 - Dy_1^2)(x_2^2 - Dy_2^2) = k^2 \);

e) by (\( d - 1 \)) and (3) we see that \( (\frac{x_3}{k})^2 - D (\frac{y_3}{k})^2 = 1 \) is a solution.

2. i) \( x_3^2 - Dy_3^2 = (x_3 + y_3\sqrt{D})(x_3 - y_3\sqrt{D}) \)
\[ = (x_1^2 - Dy_1^2)(x_2^2 - Dy_2^2) = 1 ; \]
ii) this is clear since the $x$ and $y$ appear in (1) only to the $2^{nd}$ power and, therefore, either one or both of $x, y$ may be changed to their negative;

iii) from $1 < x + y\sqrt{5}$ we have $0 < x - y\sqrt{5} = \frac{1}{x + y\sqrt{5}} < 1$ and $-1 < -x + y\sqrt{5} < 0$; adding each of these new inequalities to the given inequality yields $1 < 2x$ and $0 < 2y\sqrt{5}$ from which our conclusion is immediate;

iv) let $x + y\sqrt{5}$ be a positive solution; then for suitable $k$ we have $(x_0 + y_0\sqrt{5})^k < x + y\sqrt{5} < (x_0 + y_0\sqrt{5})^{k+1}$; multiplying by $(x_0 + y_0\sqrt{5})^{-k}$ yields $1 \leq x' + y'\sqrt{5} = (x + y\sqrt{5})(x_0 + y_0\sqrt{5})^{-k} < x_0 + y_0\sqrt{5}$; if $x' + y'\sqrt{5}$ is not 1 then, since by (iii), $x' > 0$, $y' > 0$ we would have a positive solution smaller
than the smallest positive solution; hence
\( x' + y' \sqrt{b} = 1 \) and, therefore, \( x + y \sqrt{b} = (x_0 + y_0 \sqrt{b})^k \);

\( v \) this follows from (ii), (iv), and the fact
that \( x_0 - y_0 \sqrt{b} = \frac{1}{x_0 + y_0 \sqrt{b}} \).

3. i) \( x^2 - 3y^2 = -1 \) is not solvable because if
it were the congruence \( x^2 \equiv -1 \pmod{3} \) would
be solvable; but 0, 1, 2 fail to satisfy the
congruence;

\( ii \) this parallels the details of \( \# 2 \);

\( iii \) if \( \alpha + \beta \sqrt{b} \) is the fundamental solution
of (1) then \( (\alpha + \beta \sqrt{b})(x' + y' \sqrt{b}) \) is a solution
of (2) and hence equals \( (x' + y' \sqrt{b})^{2k+1} \) for some
positive integer \( k \); thus \( \alpha + \beta \sqrt{b} = (x' + y' \sqrt{b})^{2k} \)
and its fundamental character dictates that
\( k = 1 \).
4. i) If \( x^2 - Dy^2 = 1 \) then \((\sigma x)^2 - D(\sigma y)^2 = \sigma^2 \);

ii) direct computation;

iii) consider the equation \( x^2 - 58y^2 = 9 \) with
\[
\sqrt{D} = 61 + 8 \sqrt{58};
\]

iv) when \( \sigma^2 \mid D \) then \( \sigma \mid x \) as we see from (3); the rest is easily seen by computation;

v-a) this is clear;

b) \( 4D \equiv \sigma^2 \pmod{4\sigma^2} \) yields \( D \equiv \rho^2 \pmod{4\rho^2} \); hence \( D = D'\rho^2 \) and \( D' \equiv 1 \pmod{4} \);

c) from \( x^2 - Dy^2 = x^2 - D'\rho^2y^2 = \sigma^2 = 4\rho^2 \),
we see \( \rho \mid x \); hence \( (\frac{x}{\rho})^2 - D'y^2 = 4 \); but, by (b),
\( D' \) is odd so \( \frac{x}{\rho} \) and \( y \) have the same parity;

d) \[ x_3 = \frac{x_1x_2 + Dy_1y_2}{\sigma} = \rho^2 \frac{x_1x_2 + Dy_1y_2}{2\rho} = \rho \frac{x_1x_2 + Dy_1y_2}{2}, \]
\[ y_3 = \frac{x_1y_2 + x_2y_1}{2}; \text{ now} \]
observe that \( x_i' \) and \( y_i \) have the same parity for \( i = 1, 2 \) and the conclusion follows since \( D \) is odd;

\[
\begin{align*}
\text{vi)} \quad & \frac{1}{\alpha} \leq \frac{x - y\sqrt{D}}{\alpha} < 1, \quad -1 < -\frac{x + y\sqrt{D}}{\alpha} \leq -\frac{1}{\alpha} \\
& \text{so } \frac{2x}{\alpha} > 1, \quad \frac{2y\sqrt{D}}{\alpha} > 0.
\end{align*}
\]

5. i) By direct computation;

\[
\text{\( \ddot{\text{w}} \)) if } x + y\sqrt{D} \text{ is a rational solution put } \quad r = \begin{cases} 
\frac{1-x}{y} & \text{if } y \neq 0 \\
0 & \text{if } y = 0
\end{cases} \\
\text{then } \frac{D + r^2}{D - r^2} = x \text{ and } \frac{-2r}{D - r^2} = y;
\]

\[
\text{\( \dddot{\text{w}} \)) } x = 8, \ y = 3;
\]

\[
\dot{\text{w}} \) direct computation.
\]
6. i) The fundamental solutions to these equations are, respectively, \(1 + \sqrt{2}\) and \((1 + \sqrt{2})^2 = 3 + 2\sqrt{2}\); thus all solutions are given by, respectively,

\[(1 + \sqrt{2})^{2n+1} = (1 + \sqrt{2})(3 + 2\sqrt{2})^n\text{ and } (3 + 2\sqrt{2})^n;\]

ii) If \(S_n = a + (a + 1)\) then \(a^2 + (a + 1)^2 = h_n^2\) so \(S_n^2 + 1 = (2a + 1)^2 + 1 = 2(a^2 + (a + 1)^2) = 2h_n^2\) and, therefore, \(S_n + h_n\sqrt{2} = (1 + \sqrt{2})(3 + 2\sqrt{2})^n\), where we have used (i) in the form \(S_n^2 - 2h_n^2 = -1;\)

iii) \(\frac{(2x + 1) + \sqrt{2})}{(3 + 2\sqrt{2})}\)

\[= \left(6x + 4x + 3\right) + (4x + 3x + 2)\sqrt{2}\]
so the "next Pythagorean triple" following

\((x, x + 1, z)\) is \((3x + 2z + 1, 3x + 2z + 2, 4x + 3z + 2);\)

iv) follows from (i) \(- (iii);\)

v) \((3, 4, 5)\), \((20, 21, 29)\), \((119, 120, 169)\),

\((696, 697, 985)\).
Weyl’s Theorem on Uniform Distribution

Solutions

1 i-a, b) These are clear from the definition of \( X_{[a,b]} \);

\[ \lim_{n \to \infty} \frac{n}{n} \exists \ f \to \int f \] then

\[ \lim_{n \to \infty} \frac{n}{n} \exists \ 6-a \text{ and, therefore, } \{ s_n \} \text{ is uniformly distributed}; \]

\[ \exists \text{ immediate from the definitions.} \]

2. Let \( \varepsilon > 0 \) be given and choose \( g, h, n \) satisfying the given conditions and

\[ \int g - \varepsilon \leq \frac{1}{n} \sum_{m=1}^{n} g(s_m), \]

\[ \frac{1}{n} \sum_{m=1}^{n} h(s_m) \leq \int h + \varepsilon; \]

\[ \int f - 2 \varepsilon < \int g - \varepsilon \leq \frac{1}{n} \sum_{m=1}^{n} f(s_m) \leq \int h + \varepsilon < \int f + 2 \varepsilon, \]

and, therefore,

\[ \frac{1}{n} \sum_{m=1}^{n} f(s_m) - \int f < 2 \varepsilon; \]

this proves \( f(s_n) \to \int f \).
3. Using # 1 (ii), (iii) we see that because of the additive and homogeneous properties of the arithmetic mean and of the integral the result is true whenever \( f \) is a step function; since for any Riemann integrable \( f \) the hypotheses of \#2 are realizable with \( g \) and \( h \) step functions the desired conclusion follows immediately from \#2.

4. i) This is clear since when \( u \) and \( v \) are real, 
\[
\int (u + iv) = \int u + i \int v ;
\]
ii) by (i), 
\[
f (s_n) \sim \int_0^1 e^{2 \pi i k x} \, dx = 0 .
\]

5. i) \( D \) implies \( e^{2 \pi i k s_n} \sim 0 \) which, in turn, implies each of

\[(*) \cos 2 \pi k s_n \sim 0 \text{ and } \sin 2 \pi k s_n \sim 0 ; \]

but \( T(x) = \sum_{k \in \mathbb{Z}} (a_k \cos 2 \pi k x + b_k \sin 2 \pi k x) \) and, therefore, \( \frac{1}{n} \sum_{m=1}^{n} T(s_m) = \sum_{k \in \mathbb{Z}} a_k \left\{ \sum_{m=1}^{n} \cos 2 \pi k s_m \right\} + \sum_{k \in \mathbb{Z}} b_k \left\{ \sum_{m=1}^{n} \sin 2 \pi k s_m \right\} ; \)
hence, since the expressions in the curly brackets tend to 0, we conclude $T(s_n) \sim 0$;

ii) to go the other way we see that if $T(s_n) \sim 0$ for all trigonometric polynomials with zero constant term then both assertions of (x) are true and, thus, $e^{2\pi i \xi s_n} \sim 0$;

iii) immediate from (i) and (ii);

iv) if $T(x) = a_o + T(x)$ and $T(s_n) \sim 0$ then
\[
\frac{1}{n} \sum_{m=1}^{n} T(s_m) = a_o + \frac{1}{n} \sum_{m=1}^{n} T(s_m) \rightarrow a_o + \int_0^1 T = \int_0^1 T;
\]
on the other hand, since all trigonometric polynomials certainly include those with zero constant term the opposite direction is obvious;

v) for $f$ continuous and $\epsilon > 0$ there exists a trigonometric polynomial $T$ such that $|f - T| < \frac{\epsilon}{2}$;
putting \( q = \tau - \frac{\pi}{6} \), \( h = \tau + \frac{\pi}{6} \) we see that all the conditions of \#2 are satisfied so we may conclude \( f(s_n) \sim \int f \);

vi) given a characteristic function \( \chi \) of a subinterval of \([0,1]\) we may choose continuous \( g \) and \( h \) satisfying the conditions of \#2 (we are using (v) here) and, therefore, by \#2 \( \chi(s_n) \sim \int \chi \); but then the conclusion follows by \#1(ii);

vii) this is a restatement of \#4 and (vi).

6. i) \[ \sum_{m=1}^{n} e^{2\pi i k_m e^{2\pi i k_m}} = e^{2\pi i k_m} \left( \frac{e^{2\pi i k_m}}{e^{2\pi i k_m} - 1} \right) \]

since the right side is bounded as a function of \( n \) we see that on dividing it by \( n \) the resulting expression tends to 0 as \( n \to \infty \); since this is true for all \( k \geq 0 \), the sequence \( \{s_n\} \) is uniformly distributed, by Weyl's theorem, \#5(vii);
\[ \frac{1}{n} \sum_{k=1}^{n} e^{2\pi i k s_n} = \frac{1}{n} \sum_{k=1}^{n} e^{2\pi i k (m\alpha + \beta)} = \frac{1}{n} e^{2\pi i k \beta} \left( \sum_{m=1}^{n} e^{2\pi i km\alpha} \right), \]

and since the sum on the right again tends to 0 as \( n \to \infty \) we conclude, as in (i), that \( \{ s_n \} \) is uniformly distributed.

7. i) \( n(a, b) = n(0, b) - n(0, a) \) and, therefore,
\[
\lim_{n \to \infty} \frac{n(a, b)}{n} = \lim_{n \to \infty} \frac{n(0, b) - n(0, a)}{n} = \lim_{n \to \infty} \frac{n(0, b)}{n} - \lim_{n \to \infty} \frac{n(0, a)}{n} = b - a;
\]
the opposite direction is clear;

ii) suppose \( 0 < a < 1, 0 < \epsilon < \min \{ a, 1-a \} \);
then, for \( n > N > \frac{1}{\epsilon} \),
\[
n_\alpha(0, a-\epsilon) - N_\beta(0, a-\epsilon) \leq n_\alpha(0, a) \leq n_\beta(0, a+\epsilon) + N;
\]
dividing throughout by \( n \) and allowing \( n \) to increase without bound we find \( \frac{n_\alpha(0, a)}{n} - a \) may be made as small as we wish if only we choose \( n \) sufficiently large; consequently
\[
\lim_{n \to \infty} \frac{n_\alpha(0, a)}{n} \text{ exists and equals } a \; ; \text{ the conclusion now follows from (i)}.\]
(iii) it is obvious that if some enumeration of $S$ is uniformly distributed then $S$ is dense in $[0,1]$; on the other hand suppose $S$ is dense in $[0,1]$ and $\{\beta_n\}$ is any uniformly distributed sequence; choose a sequence $\{\alpha_n\}$ from $S$ such that $|\alpha_n - \beta_n| < \frac{1}{n}$ and the $\alpha_n$ are distinct; now enumerate $S - \{\alpha_n\}$ to get $\{\delta_n\}$; finally, place $\delta_j$ into the $\{\alpha_n\}$ sequence so as to have $\delta_j$ occupy the $j^{th}$ position in the resulting sequence; clearly since $\{\alpha_n\}$ is uniformly distributed, by (ii), so also will the new sequence with the $\delta_j$ inserted.

8. i) Study the diagram:
ii) note that if \(p-r=p-s=q\) then \(r=s\) and one obtains \(q\) for the pairs \((p, r)\) equal to:
\[(q, 0), (q+1, 1), (q+2, 2), \ldots, (q+H-1, H-1)\];
thus there are exactly \(H\) such pairs; if \(p-r\neq p-s\) then, say, \(p-r=q\), \(p-s=q+h\), \(h > 0\); then
\[1 \leq q \leq q-h\] and \(p-s=p-r+h\) so \(r-s=h\); thus, terms \(a_q \bar{a}_{q,h}\) are obtained from the pairs \((r, s)\) equal to: \((h, 0), (h+1, 1), \ldots, (H-1, H-1-h)\);
thus there are exactly \(H-h\) such pairs; the same argument works for \(a_q a_{q,h}\); from these observations the desired conclusion follows.

9. Using \#8 and the Schwarz' inequality we have
\[
H^2 \left| \sum_{s \in \mathbb{Q}+a} a_q \right|^2 = \left| \sum_{s \in \mathbb{Q}+a} a_q \right|^2 = \left| \sum_{s \in \mathbb{Q}+a} (1 \cdot \sum_{s \in \mathbb{Q}+a} a_{p-r}) \right|^2 \\
\leq \left( \sum_{s \in \mathbb{Q}+a} (1^2) \sum_{s \in \mathbb{Q}+a} \left| \sum_{s \in \mathbb{Q}+a} a_{p-r} \right| \right)^2 \\
= (H+Q-1) \sum_{s \in \mathbb{Q}+a} a_{p-r} \bar{a}_{p-s} \\
\left( \sum_{s \in \mathbb{Q}+a} a_{p-r} \bar{a}_{p-s} \right) \\
= (H+Q-1) \sum_{s \in \mathbb{Q}+a} \left| a_q \right|^2 + \left( H+Q-1 \right) \sum_{s \in \mathbb{Q}+a} \left| a_q \bar{a}_{q+h} \right|^2 \\
= (H+Q-1) H \sum_{s \in \mathbb{Q}+a} \left| a_q \right|^2 + 2 (H+Q-1) \sum_{s \in \mathbb{Q}+a} \left| a_q \bar{a}_{q+h} \right|^2.
\]
10. i) Put $\alpha_q = e^{2\pi i s_q}$, then, for $0 < |s| < Q$, using $s_q$,
\[
\frac{1}{Q^2} \sum_{1 \leq s \leq Q} e^{2\pi i s \alpha} \leq \frac{1}{\sqrt{Q}} + 2 \sum_{0 \leq q < Q} \left| \frac{1}{\sqrt{Q}} \sum_{1 \leq s \leq Q} e^{2\pi i (s \alpha + \frac{q}{Q} - \frac{s}{Q})} \right|
\]
for fixed $\alpha$ the right side tends to $\frac{1}{\sqrt{Q}}$ as $Q \to \infty$; since this is true for any $\alpha$ the left side tends to 0 and we are done;

ii) by our earlier work we know $e^{2\pi i k (s_n + h_n - s_n)} \sim 0$ for all positive integers $k$ and $h$; thus, by (i), $e^{2\pi i k s_n} \sim 0$ for all positive integers $k$; the conclusion now follows from Weyl's theorem, #5(vii).

11. (A) Suppose $\alpha_r$ is irrational; when $r=1$ the result follows from #6(ii); thus suppose $r > 1$ and that the result has been proved for $r-1$; for each fixed positive integer $h$ the quantity $f(n+h) - f(n)$ is a polynomial of degree $r-1$ with irrational leading coefficient $\alpha_r$; thus the result follows from that for $r-1$ and #10(ii);
(B) suppose \( a_1, \ldots, a_{s+1} \) are rational and \( a_s \) is irrational, \( 0 < s < r \); let \( M \) be such that \( Ma_1, \ldots, Ma_{s+1} \) are integers; if we can show \( \{ f(Mn+m) \} \) is uniformly distributed for each \( m = 0, 1, \ldots, M-1 \) then \( \{ f(n) \} \) is uniformly distributed; but, modulo 1,

\[
f(Mn+m) = a_0 + a_1(Mn+m) + \cdots + a_r(Mn+m)^r
\]

\[
\equiv a_0 + a_1(Mn+m) + \cdots + a_s(Mn+m)^s + a_{s+1}m^{s+1} + \cdots + a_rm^r
\]

\[
\equiv \beta_0 + \beta_1n + \cdots + \beta_sn^s,
\]

where the \( \beta_j \) are independent of \( n \); in particular, \( \beta_s = M^s a_s \) is irrational; this is the first case of the result (see (A)) so \( \{ f(Mn+m) \} \) is uniformly distributed for each \( m \) and, as we have already observed, this implies \( \{ f(n) \} \) is uniformly distributed.
1. i-a) If \( d_1, \ldots, d_g \) are the divisors of \( m \) then the coefficient of \( x^m \) on the right side, after multiplying out and collecting terms, is \( a_{d_1} + \cdots + a_{d_g} \); thus the right side is \( \sum_{m=1}^g (\sum_{d|m} a_d) x^m \); identifying coefficients on left and right yields the desired conclusion.

6) This is shown by induction; for \( s = 1 \) and any \( t \) this follows from (a); suppose true for \( s < n \) and all \( t \); then (\( s=n, t \geq 1 \))

\[
0 = \sum_{d|n, t} a_d = \sum_{d|m, \delta|t} a_d \delta = \sum_{d|m} \delta \sum_{\delta|t} a_d \delta + a_{nt}
\]

\[
= (\sum_{d|m} a_d \lambda \sum_{\delta|t} a_\delta) - a_n a_t + a_{nt} = a_{nt} - a_n a_t;
\]

\( c) \quad a_{np^e} = a_1 = 1 \); by (a), \( a_1 + a_p = 0 \) so \( a_p = -1 \); also by (a), \( a_1 + a_p + a_{p^2} = 0 \) so \( a_{p^2} = 0 \); if \( a_{p^k} = 0 \) for \( 2 \leq k \leq n \), then, by (a), \( a_1 + \cdots + a_{pn} + a_{pn+1} = 0 \) so \( a_{pn+1} = 0 \);

\( d) \quad this \ is \ immediate \ from \ (6) \ and \ (c); \)
ii-a) This follows from the fact that
\[ f(x^m) = \frac{x^m}{1-x^m} \] and the definition of the \( a_j \);

b) for \( x = \frac{1}{10} \) the result in (a) is true not only formally but also in the sense of convergence; putting \( x = \frac{1}{10} \) in the expression in (a) yields
\[
\frac{1}{10} = \sum_{m=1}^{\infty} \frac{g_{am}}{10^{m-1}} = \frac{1}{9} - \frac{1}{99} - \frac{1}{999} - \frac{1}{99999} + \frac{1}{999999} - \cdots
\]
\[
- \frac{1}{999999} + \frac{1}{9999999999} - \cdots ;
\]

c) multiplying the expression in (b) by 9 and then subtracting from 1 yields
\[
\frac{1}{10} = 1 - \sum_{m=1}^{\infty} \frac{g_{am}}{10^{m-1}} = \frac{1}{11} + \frac{1}{111} + \frac{1}{11111} + \cdots
\]
\[
+ \frac{1}{1111111} - \frac{1}{11111111111} + \cdots .
\]

2. i) This follows from the definition and from *1(i-6,d) since these show \( \nu(n) = a_n \) and that
\( a_n \) is a multiplicative function.

ii) If \( n = p_1^{a_1} \cdots p_r^{a_r} \) then
\[
\sum_{d \mid n} \nu(d)f(d) = \sum_{d \mid p_1^{a_1} \cdots p_r^{a_r}} \nu(d)f(d) = (1-f(p_1)) \cdots (1-f(p_r));
\]
(a) - (d) put \( f(d) \) respectively equal to \( 1, \frac{1}{d}, n/d \) in (ii); in (c) also recall the expression for \( \varphi(n) \); compare this with \( \text{tw} \# 18 \)(viii).

3. i). From left to right we have

\[
\sum_{d \mid n} N(d) \frac{\varphi(n)}{d} = \sum_{d \mid n} N(d) \sum_{d \mid m} q(m) = \sum_{m \mid n} q(m) \sum_{d \mid m} N(d) = q(n);
\]

in the other direction

\[
\sum_{d \mid n} q(d) = \sum_{d \mid m} N(m) \frac{\varphi(m)}{m} = \sum_{d \mid m} N(d) \frac{\varphi(m)}{m} = \sum_{m \mid n} \sum_{d \mid m} N(d) = \sum_{m \mid n} q(m) \sum_{d \mid m} N(d) = \sum_{m \mid n} q(m) \sum_{d \mid m} N(d) = f(n);
\]

a) if \( n = p_1^{\alpha_1} \cdots p_k^{\alpha_k} \) then

\[
\sum_{d \mid n} \varphi(d) = \frac{\varphi(n)}{n} \sum_{d \mid n} \varphi(d) = \sum_{j=1}^{k} \alpha_j \ln p_j = \ln n;
\]

now apply (i) and use \( \text{tw} \# 2 \)(ü-a);

b) apply (i) to the expression \( \varphi(n) = \sum_{d \mid n} N(d) \frac{n}{d} \)

obtained in \( \text{tw} \# 2 \)(ü-c); (compare with \( \text{viii} \# 19 \));

c) imitate the proof of (i) exactly; note that if all quantities were positive we could take logs and obtain (i) from this result;
apply (c) to the formula \( x^n - 1 = \prod_{d \mid n} \Phi_{d}(x) \)
of \( x^{IV} 17(i) \); compare with \( x^{IV} 18(vii) \);

e) from (i) we see that \( \Phi(n) = \sum_{d \mid n} \mathcal{N}(d) \mathcal{N}(\frac{n}{d}) \);

if \( n \) contains \( p^3 \) for some \( p \) then either \( d \) or \( \frac{n}{d} \)
contains \( p^2 \) so each summand is 0 and \( \Phi(n) = 0 \);

otherwise, if \( n = s^2v \), \( (s, v) = 1 \), we have

\[
\Phi(n) = \sum_{d \mid n} \mathcal{N}(sd) \mathcal{N}(\frac{n}{sd}) = \sum_{d \mid n} \mathcal{N}(sd) \mathcal{N}(s \frac{v}{d})
\]

\[
= \sum_{d \mid n} \mathcal{N}(d) \mathcal{N}(\frac{v}{d}) = \sum_{d \mid n} (-1)^t \begin{cases} (-2)^t & \text{if } v > 1 \\ 1 & \text{if } v = 1 \end{cases}
\]

\[
= \sum_{d \mid n} \mathcal{N}(d) \mathcal{N}(\frac{v}{d})
\]

now apply (i) to obtain the desired result;

ii) \( q(n) = \sum_{d \mid n} \mathcal{N}(d) \mathcal{N}(\frac{n}{d}) = \sum_{d \mid n} \mathcal{N}(sd) \mathcal{N}(\frac{n}{sd}) \)

\[
= \sum_{d \mid n} \mathcal{N}(d) \mathcal{N}(\frac{n}{d}) = \sum_{d \mid n} \mathcal{N}(d)
\]

a) put \( \Psi(x) = e^{2\pi i x} \) in (ii) and observe that

\( q(1) = 1 \), \( q(n) = 0 \) for \( n > 1 \);

b) with \( S_{k}(n) / n^k = \sum_{(r, n) = 1} \mathcal{N}(\frac{r}{n})^k \)

\( q(n) = \sum_{r \mid n} (\frac{r}{n})^k = \frac{1 + \cdots + n^k}{n^k} \)

use (ii) to obtain

\( S_{k}(n) / n^k = \sum_{d \mid n} \mathcal{N}(d) q(\frac{n}{d}) \), from which the desired

result follows;
1) put $k = 1$ in (b) and use $\sum_{2(\text{ii}) - a, c}^2$ plus $1 + 2 + \ldots + d = \frac{d(d+1)}{2}$;
2) put $k = 2$ in (b) and use $\sum_{2(\text{ii}) - a, b, c}^2$ plus $1^2 + 2^2 + \ldots + d^2 = \frac{d(d+1)(2d+1)}{6}$;
3) put $k = 3$ in (b) and use $\sum_{2(\text{ii}) - a, b, c}^2$ plus $1^3 + 2^3 + \ldots + d^3 = \frac{d^2(d+1)^2}{4}$;
4) apply (i) to the result in (b);
5) use (ii) with $f(n) = \sum_{\frac{n!}{r_s n!}} \ln \frac{n}{n!}$, $q(n) = \ln \frac{n!}{n^n}$;

\[ \sum_{d} N(d) \sum_{\frac{N(d)}{d}} \phi(k_i) = \sum_{i=1}^{N} f(k_i) \sum_{d} N(d) = \alpha f(1); \]
\[ \phi(x, y) = \sum_{d} N(d) S_d; \]
1) $1 = \phi(n, n) = \sum_{m \leq n} N(m) \left[ \frac{m}{n} \right] = \sum_{m \leq n} N(m) \left[ \frac{m}{n} \right]$;
2) $| \sum_{m \leq n} \frac{N(m)}{m} | = \left| \frac{1}{n} \sum_{m \leq n} N(m) \left( \frac{m}{n} - \left[ \frac{m}{n} \right] \right) + \frac{1}{n} \right|$
   $\leq \frac{n+1}{n} + \frac{1}{n} = 1$, where we have used (1) at the 1st equality;
3) $\pi(x) - \pi(\sqrt{x}) + 1 = \phi(x, \sqrt{x})$; compare VIII*24.
4. i) \( \sum_{mn} n(n) h(x, mn) = \sum_{m} \sum_{n} n(n) h(x, mn) = \sum_{m} n(n) \sum_{n} h(x, m) = \sum_{m} h(x, m) \sum_{n} n(n) = h(x, 1) \);

\( \hat{w} \) from left to right we have, using (i) at the last equality,

\[ \sum_{n \in x} n(n) p(n) q(x/n) = \sum_{n \in x} n(n) p(n) \sum_{m \in x} p(m) f(x/mn) = \sum_{m \in x} p(nm) f(x/mn) = f(x) \]

in the other direction, using (i) at the last equality,

\[ \sum_{n \in x} p(n) f(x/n) = \sum_{n \in x} p(n) \sum_{m \in x} n(m) p(m) q(x/nm) = \sum_{m \in x} n(m) p(nm) q(x/nm) = q(x) \]

\( \hat{w} \) from left to right we have

\[ \sum_{n=1}^{\infty} n(n) q(nx) = \sum_{n=1}^{\infty} n(n) \sum_{m=1}^{\infty} f(mnx) = \sum_{m=1}^{\infty} f(mx) \sum_{n=1}^{\infty} n(n) = f(x) \]

in the other direction,

\[ \sum_{m=1}^{\infty} f(mx) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} n(n) q(mnx) = q(x) \]
iv) from left to right we have
\[ \sum_{t \in \mathcal{E}} N(t) F(t d) = \sum_{t \in \mathcal{E}} N(t) \sum_{s \in \mathcal{E}} G(s t d) \]
\[ = \sum_{v \in \mathcal{E}} G(v d) \sum_{t \in \mathcal{E}} N(t) = G(d) ; \]

in the other direction,
\[ \sum_{d \in \mathcal{E}} G(d) = \sum_{d \in \mathcal{E}} \sum_{t \in \mathcal{E}} N(t) F(t d) \]
\[ = \sum_{v \in \mathcal{E}} F(v d) \sum_{t \in \mathcal{E}} N(t) = F(d) . \]
Some Analytic Methods - Solutions

1. i) \[
\sum_{m=1}^{N} F(m) (q(m+1) - q(m)) = \\
\sum_{m=M+1}^{N} F(m) q(m+1) - \sum_{m=M+1}^{N} F(m) q(m) = \\
F(N) q(N+1) + \sum_{m=M}^{N} (F(m+1) - F(m)) q(m) - F(M) q(M+1) = \\
F(N) q(N+1) - \sum_{m=M+1}^{N} F(m) q(m), \text{ since } F(M) = 0;
\]

ii) \[
\left| \sum_{m=M+1}^{N} f(m) q(m) \right| \leq \\
|F(N)| q(N) + \left| \sum_{m=M+1}^{N-1} F(m) \right| |q(m+1) - q(m)| \\
\leq \max_{m \leq \infty} |F(m)| \left\{ q(N) + \sum_{m=M+1}^{N-1} q(m+1) - q(m) \right\} \\
= \left\{ \begin{array}{ll}
\max_{m \leq \infty} |F(m)| \left\{ q(N) + q(M+1) - q(N) \right\} & \text{if } q \text{ is decreasing;} \\
\max_{m \leq \infty} |F(m)| \left\{ q(N) - q(M+1) + q(N) \right\} & \text{if } q \text{ is increasing;}
\end{array} \right.
\]
from which the desired result follows;

iii-a) the result in (ii), first part, shows the sequence of partial sums is a Cauchy sequence;

b) \[
\sum_{n=1}^{\infty} f(n) q(n) = \sum_{n=x}^{\infty} f(n) q(n) + \sum_{n=E+1}^{\infty} f(n) q(n) \\
\text{and, since } \left| \sum_{n=E+1}^{\infty} f(n) q(n) \right| = q(\lceil x \rceil) \max_{m \leq \infty} |F(m)|, \\
\text{we know } \sum_{n=E+1}^{\infty} f(n) q(n) = O(q(\lceil x \rceil));
\]
w) let \( r \) be the largest index \( m \) for which \( \lambda_m \leq x \); then 
\[
\int_{\lambda_1}^{x} F(t) q'(t) \, dt = \sum_{m=1}^{r} \int_{\lambda_m}^{\lambda_{m+1}} F(t) q'(t) \, dt + \int_{\lambda_r}^{x} F(t) q'(t) \, dt \\
= \sum_{m=1}^{r} F(\lambda_m) \int_{\lambda_m}^{\lambda_{m+1}} q'(t) \, dt + F(\lambda_r) \int_{\lambda_r}^{x} q'(t) \, dt \\
= \sum_{m=1}^{r} F(\lambda_m) (q(\lambda_{m+1}) - q(\lambda_m)) + F(x)(q(x) - q(\lambda_r)) \\
= \sum_{m=1}^{r} (F(\lambda_{m+1}) - F(\lambda_m)) q(\lambda_m) + F(x) q(x) \\
= F(x) q(x) - \sum_{m=1}^{r} f(m) q(\lambda_m) ;
\]

v) in (iv) we put \( \lambda_i = a, \lambda_j = a + j - 1, f(m) = 1 \) for all \( m \) and obtain
\[
\sum_{m=0}^{x} q(m) = ([x] - a + 1) q(x) - \int_{a}^{[x] - a + 1} q'(t) \, dt,
\]
and, after noting that
\[
\int_{a}^{x} q(t) \, dt = x q(x) - a q(a) - \int_{a}^{x} q'(t) \, dt,
\]
we see that this agrees with the given expression;

vi) by (v),
\[
|\sum_{m=0}^{x} q(m) - \int_{a}^{x} q(t) \, dt| \leq \int_{a}^{x} |q'(t)| \, dt + |q(a)| + |q(x)| \\
= \pm (q(x) - q(a)) + |q(a)| + |q(x)| = O(|q(a)| + |q(x)|) ;
\]
vii) \( \sum_{n \neq x} q(n) \cdot \int_{x}^{\infty} q(t) \, dt - c = 
\int_{x}^{\infty} (t - \lfloor t \rfloor) q(t) \, dt - (x - \lfloor x \rfloor) q(x) \)

and, since \( |t - \lfloor t \rfloor| < 1 \), \( \int_{x}^{\infty} q(t) \, dt = q(x) \) we know the right side is, in absolute value, smaller than \( 2 |q(x)| \); we are using \( q(x) \to 0 \) as \( x \to \infty \) in guaranteeing the infinite integrals exist.

2. i) Put \( a = 1 \), \( q(x) = x^{-s} \) in \( \# 1(vi) \);

ii) put \( a = 1 \), \( q(x) = \frac{1}{x} \) in \( \# 1(vii) \) to obtain the expression for \( \sum_{n \neq x} \frac{1}{n} \) with \( \gamma = 1 - \int_{1}^{\infty} \frac{x - \lfloor x \rfloor}{1} \, dt \);

the other expression for \( \gamma \) follows from the obtained expression;

iii) put \( a = 1 \), \( q(x) = \ln x \) in \( \# 1(vi) \);

iv) \( \sum_{n \neq x} \ln \frac{x}{n} = \sum_{n \neq x} \ln x - \sum_{n \neq x} \ln n \\
= \lfloor x \rfloor \ln x - (x \ln x - x + O(\ln x)) = (\lfloor x \rfloor - x) \ln x + x + O(\ln x), \\
and this last is clearly \( O(x) \);
v) First of all note
\[
\frac{1}{x} \sum_{p \leq x} \ln p \left\{ \left[ \frac{x}{p} \right] + \left[ \frac{x}{p^2} \right] + \ldots \right\} \leq \sum_{p \leq x} \frac{\ln p}{p} + \sum_{p \leq x} \ln p \left\{ \frac{1}{p} + \frac{1}{p^2} + \ldots \right\}
\]
\[
= \sum_{p \leq x} \frac{\ln p}{p} + \sum_{p \leq x} \frac{\ln p}{p(p-1)};
\]
using XIV#11(v) the last sum tends to a limit as \( x \to \infty \) and, therefore, our 1st equality is proved; the 2nd equality is immediate from the definition of \( \Lambda \); using XIX#3(i-a) we see that \( \ln n = \sum_{d|n} \Lambda(d) \) so \( \frac{1}{x} \sum_{n \leq x} \ln n = \frac{1}{x} \sum_{n \leq x} \sum_{d|n} \Lambda(d) \); for each \( d \leq x \), \( \Lambda(d) \) will occur in the last sum precisely as many times as there are \( n \leq x \) with \( d|n \); i.e., \( \frac{1}{x} \sum_{n \leq x} \sum_{d|n} \Lambda(d) = \frac{1}{x} \sum_{d \leq x} \left[ \frac{x}{d} \right] \Lambda(d) \); but this, with different notation, yields our 3rd equality; the last equality is a consequence of (iii);

vi) the 1st equality is contained in (v); for the 2nd we have, where we use (v) and the Chebyshev inequality, see XIV#10(ix), the inequality
\[
\sum_{n \leq x} \frac{\Lambda(n)}{n} = \frac{1}{x} \sum_{n \leq x} \left( \Lambda(n) - \left[ \frac{x}{n} \right] \right) \Lambda(n) + \frac{1}{x} \sum_{n \leq x} \left[ \frac{x}{n} \right] \Lambda(n)
\]
\[
\leq \frac{B}{n} \cdot \ln x + \ln x + O(1) = \ln x + O(1);
\]

vii) put \( \lambda_j = p_j \), \( f(m) = 1 \) for all \( m \),
\[ q(x) = \frac{\ln x}{x} \ln x \ln 1 (w) ; \text{ then} \]
\[ \sum_{p \leq x} \frac{\ln p}{p} = \pi(x) \frac{\ln x}{x} \lim_{x \to \infty} \frac{1}{x^2} \ln t \]
\[ = O(1) + \sum_{2}^{\pi(t)} \frac{\ln t - 1}{t^2} \ln t ; \]
the result follows immediately by taking a difference.

3. i) The 1st equality follows immediately from \( \# 2 (vii) \) by taking a difference; the 2nd equality is \( \# 2 (vii) \); the 1st inequality follows (for \( N \) sufficiently large) from our assumption that the \( \lim_{x \to \infty} \frac{\pi(x)}{x / \ln x} \) exists and is less than 1; the 2nd inequality follows from suppressing the term \( \frac{1}{t \ln t} \) and integrating; the result is false because it says that for sufficiently large \( N \),
\[ \frac{1-\Omega}{2} \ln N = O(1) ; \]

ii) parallel to (i);

iii) immediate from (i) and (ii).
4. i) \[ \sum_{d \leq N} \sigma(n) = d + 2d + \ldots + \left[ \frac{N}{d} \right]d \]
\[ = \frac{d}{2} \left[ \frac{N}{d} \right] \left( \left[ \frac{N}{d} \right] + 1 \right) = \frac{d}{2} \left( \frac{N}{d} + \Theta(1) \right)^2 \]

ii) clearly \( N^* = \sum_{n \leq N} \varphi(n) \); now, using xxii \( \approx \) 2(ii-c),
we find this latter expression equals
\[ \sum_{n \leq N} \sum_{d | n} \sigma(d) \frac{n}{d} = \sum_{d \leq N} \sum_{n \leq N} \frac{n \sigma(d)}{d} \]

iii) substituting the result of (i) into (ii)
yields \( N^* = \sum_{n \leq N} \frac{n \sigma(d)}{d} \left( \frac{N}{d} + \Theta(1) \right)^2 \)
\[ = \frac{N^2}{2} \sum_{d \leq N} \frac{n \sigma(d)}{d^2} + \Theta(1) \]
where we have used xxii \( \approx \) 3(iii-2); this last
equals \( \frac{N^2}{2} \sum_{d \leq N} \frac{n \sigma(d)}{d^2} \]
\[ = \frac{N^2}{2} \sum_{d \leq N} \frac{n \sigma(d)}{d^2} + N^2 \varphi(N) \]
where \( \varphi(N) = - \frac{1}{2} \sum_{d \leq N} \frac{n \sigma(d)}{d^2} + \frac{1}{N^2} \Theta(N) \to 0 \) as \( N \to \infty \);
finally, note that
\[ \left( \sum_{n \leq N} \frac{1}{n^2} \right) \left( \sum_{n \leq N} \frac{n \varphi(n)}{n^2} \right) = \sum_{n \leq N} \varphi(n) \frac{1}{n^2} + \sum_{n \leq N} \varphi(n) \frac{1}{n^2} = 1 \]
so the desired result is correct ;
iv) \( N' = \frac{N(N+1)}{2} \) and \( \frac{N^2}{2N} \rightarrow 1 \) as \( N \rightarrow \infty \); therefore, using (iii), the result is immediate.

v) this is just a restatement of (iv) after replacing \( \sum_{n=1}^{\infty} \frac{1}{n^2} \) by its value \( \frac{\pi^2}{6} \).

5. i) The series is merely the Taylor expansion of \( \ln \frac{1}{1-x} \); since
\[ x \leq x + \frac{x^2}{2} + \frac{x^3}{3} + \cdots \leq x (1 + x + x^2 + \cdots) = \frac{x}{1-x} \leq 2x \]
the inequalities are correct.

ii) first we note that if either series converges it must be true that all \( x_j \) with \( j \) sufficiently large satisfy the conditions on \( x \) in (i); hence we may, without loss of generality, assume \( 0 \leq x_j \leq \frac{1}{2} \) for all \( j \); hence, by (i),
\[ \sum_{j=1}^{n} x_j \leq \sum_{j=1}^{n} \ln \frac{1}{1-x_j} \leq 2 \sum_{j=1}^{n} x_j \]
and the desired conclusion follows.
iii) this follows from (ii) and the continuity of the logarithm function since
\[ \prod_{j=1}^{\infty} \ln \frac{1}{1-x_j} = \ln \prod_{j=1}^{\infty} \frac{1}{1-x_j}. \]

6. i) If for some integer \( s \), \( |f(s)| > 1 \) then by the complete multiplicativity of \( f \) we would have \( f \) unbounded on the sequence \( s, s^2, s^3, \ldots \) and this would contradict the convergence of \( \sum_{j=1}^{\infty} f(j) \);

ii) this follows from
\[ \prod_{p \leq m} (1-f(p))^{-1} = \prod_{p \leq m} (1+f(p)+f(p^2)+\ldots) = \sum_{j=1}^{m} f(j) + \sum f(j), \]
where the 2nd sum is over all those \( j \) exceeding \( m \) and having no prime factors exceeding \( m \);

iii) this follows from (ii) by allowing \( m \) to tend to infinity.
7. i-a, b) These follow immediately from the existence of the integral \( \int_1^{\infty} x^{-s} \, dx \) and the inequality \( \int_1^{\infty} x^{-s} \, dx < \sum_{n=2}^{\infty} \frac{1}{n^s} < 1 + \int_1^{\infty} x^{-s} \, dx \);

c) from (b), \( 1 < (s-1) \zeta(s) < s \), and the result follows;

d) put \( f(x) = x^{-s} \) in \( \#6 \) (iii);

e) take logarithms in (d) and then use the equality of \( \#5 \) (i);

f) from (e) we find

\[
0 \leq \ln \zeta(s) - \sum_p \frac{1}{p^s} = \sum_{n=2}^{\infty} \frac{\zeta(n)}{n} \frac{1}{p^s n^s};
\]

but \( \sum_{n=2}^{\infty} \frac{1}{np^s} < \frac{1}{p} \sum_{n=2}^{\infty} \frac{1}{p^{s-1}} \); hence

\[
\sum_{n=2}^{\infty} \frac{1}{np^s} < \sum_p \frac{1}{p(p-1)} < \sum_{n=2}^{\infty} \frac{1}{n(n-1)} = 1 \text{ and the conclusion follows};
\]

ii-a) the result in (i-c) tells us \( \zeta(s) \) must tend to \( \infty \) as \( s \to 1^+ \); the result in (d) says this could not happen if there were only finitely many primes;
b) since \( \ln g(s) \) exists for \( s > 1 \), (i-f) shows us \( \sum_{p} \frac{1}{p^{s}} \) exists; by (i-f) we see that 
\[ \sum_{p} \frac{1}{p^{s}} \to \infty \text{ as } s \to 1^{+} ; \]
since for all \( s > 1 \), \( \sum_{p \leq n} \frac{1}{p^{s}} < \sum_{p \leq n} \frac{1}{p} \) we see that
\[ \sum_{p} \frac{1}{p} \text{ diverges} . \]

8. i-a) \[ \sum_{n=1}^{\infty} \frac{\chi(n)}{n^{s}} = 1 - \frac{1}{3^{s}} + \frac{1}{5^{s}} - \frac{1}{7^{s}} + \cdots \] is an alternating series with terms in absolute value tending strictly monotonically to \( 0 \); hence the convergence follows by the Leibniz test;

b) these follow immediately from the fact that in such a series the error made in a partial sum approximation never exceeds the magnitude of the 1st omitted term and has the same algebraic sign;

c) this follows from the uniformity of the convergence of the series in a small neighborhood of 1 ;
d) by \#7(i-c), \$s(s) \to \infty$ as $s \to 1^+$ and by (b) and (c), $L(s)$ tends to a finite positive limit; 

e) \prod_{p \equiv 3 \pmod{4}}(1 - p^{-2s})^{-1} = \sum_{n \geq 1} \frac{1}{n^{2s}}$, where the sum is over all integers $n$ all of whose prime factors are of the form $4k + 3$; thus the product, which is monotonically increasing as $s \to 1^+$, is always bounded above by \$s(2)$; thus the assertion is correct; 

f) by \#5(\iii) and \#7(i-a) all products converge; the result for \$s(s)$ now follows from the truth of the identity for all integers $n$ when all primes are restricted to be $\leq n$; the result for $L(s)$ follows from the complete multiplicativity of $\chi$, an argument like that leading to \#7(i-d) (except that one now takes $f(x) = \frac{x(x)}{\chi^2}$), and the above argument for the \$s(s)$ identity; 

g) from (f) we see that 

\$s(s)L(s) = \frac{1}{1-2s} \prod_{p \equiv 1 \pmod{4}}(1 - p^{-s})^{-2} \prod_{p \equiv 3 \pmod{4}}(1 - p^{-2s})^{-1}$,
now the left side, by (d), tends to \( \infty \) as \( s \to 1^+ \) while, by (e), the product on the far right of the right side tends to a finite limit; hence since \( \frac{1}{1 - 2^s} \) also tends to a finite limit it must be the case that \( \prod_{p \equiv 1 \pmod{4}} (1 - p^{-s})^{-2} \to \infty \) as \( s \to 1^+ \); but this implies there must be infinitely many \( 4k+1 \) primes; for the \( 4k+3 \) primes we consider \( \mathcal{S}(s) \mathcal{L}(s)^{-1} = \frac{1}{1 - 2^s} \prod_{p \equiv 3 \pmod{4}} \frac{1 + p^{-s}}{1 - p^{-s}} \); the left side tends to infinity as \( s \to 1^+ \) and therefore, so must the right, and that implies the existence of infinitely many primes of the form \( 4k+3 \);

(ii-a, b) follow from the same argument used to prove \( \#7(e, f) \);

c,d) \( \ln \mathcal{S}(s) + \chi^{-1}(a) \ln \mathcal{L}(s) = \sum_{p} \frac{1}{p^s} + \sum_{p} \frac{\chi(a) \chi(p)}{p^s} + O(1) \)

\[
= \begin{cases} 
\prod_{p \equiv 3 \pmod{4}} \frac{1}{p^s} + O(1) & \text{for } a = 4k+1; \\
\prod_{p \equiv 3 \pmod{4}} \frac{1}{p^s} + O(1) & \text{for } a = 4k+3;
\end{cases}
\]

since, using (i-c) and \( \#7(i-c) \), the left side tends to infinity as \( s \to 1^+ \) independent of \( a \) the conclusion follows.
9. i-a) Direct checking;

b) when \( a \equiv n \mod 5 \) this is clear since in this case each summand is 1 and there are 4 summands; when \( a \not\equiv n \mod 5 \) the sum is just a sum of column entrees in our table after each entry is divided by the corresponding entry in another column; direct inspection yields the result;

c) for each \( \chi \) under consideration each series breaks into a real and a complex part; the series of the two parts are each alternating and converge by the same argument used in the proof of \( \# 8 (i-a) \); that they are not zero follows as in the proof of \( \# 8 (i-b) \);

d) these follow from (c) and the alternating character of the real and complex parts of the series;

e) from the 1st formula of (d) we have

\[
\sum_{n<x} \chi(n) \frac{x}{n} = x \nu_0(\chi) + O(1);
\]

now put \( \nu(n) = \chi(n) \), \( f(x) = x \) in the Shapiro form of the Möbius inversion formula, see XXII \( \# 4 (ii) \),
to obtain
\[ x = \sum_{n \leq x} N(n) X(n) \left\{ \frac{x}{n} L_0(X) + o(1) \right\}; \]
this implies
\[ \sum_{n \leq x} \frac{N(n) X(n)}{n} = L_0(X)^{-1} \left\{ 1 - \frac{o(x)}{x} \sum_{n \leq x} N(n) X(n) \right\}; \]
the conclusion follows since \( |N(n) X(n)| = 1 \) for all \( n \) so the right hand side of this last equation is \( o(1) \);

\( i\) from \( XX11, \#3(1-a-2) \) and \( \#2(ii-a) \), we have
\[ \Lambda(n) = \sum_{d \mid n} \mu(d) \ln \frac{n}{d}; \text{ this along with the } 2^{nd} \text{ formula of } (d) \text{ yields} \]
\[ \sum_{n \leq x} \frac{X(n) \Lambda(n)}{n} = \sum_{n \leq x} \frac{N(n)}{d} \sum_{d \mid n} \mu(d) \ln \frac{n}{d} = \sum_{d \leq x} N(d) \sum_{j \leq \frac{x}{d}} \frac{\Lambda(d j)}{j} \ln j \]
\[ = \sum_{d \leq x} \frac{N(d) X(d)}{d} \sum_{j \leq \frac{x}{d}} \frac{\Lambda(d j)}{j} \ln j = \sum_{d \leq x} \frac{N(d) X(d)}{d} \left\{ L_1(X) + o \left( \frac{\ln x/d}{x/d} \right) \right\}; \]
the result now follows from \( (e) \) since \( L_1(X) \) is a constant and \( \sum_{d \leq x} \frac{N(d) X(d)}{d} o \left( \frac{\ln x/d}{x/d} \right) \) is dominated by an expression \( \frac{1}{x} \sum_{d \leq x} o \left( \frac{\ln x}{x} \right) = o(1), \) by \( \#2(\hat{w}) \);

\( ii-a \) by the definition of \( \Lambda(n) \), the 1st sum on the right is clearly equal to the left hand sum plus the 2nd sum on the right; the rest follows
from (i-\text{f}) and

\[ \sum_{j=2}^{\infty} \frac{\ln p}{p^j} = \sum_{p} \frac{\ln p}{p^2} + \sum_{p} \frac{\ln p}{p^{j+1}} < \sum_{p} \frac{\ln p}{p^2} + \sum_{j=2}^{\infty} \frac{1}{p^j} \]

\[ < \sum_{p} \frac{\ln p}{p^2} + \sum_{j=2}^{\infty} \left( \frac{1}{2^j} + \frac{1}{3^j} \right) \]

\[ < \sum_{p} \frac{\ln p}{p^2} + \frac{1}{2} + \sum_{j=2}^{\infty} \frac{1}{(j-1)j} = o(1) ; \]

6) multiplying the expression in (ii-a) by \( \chi(a)^{-1} \) and summing over all characters, including \( \chi_0 \), we find, after using (i-b),

\[ \sum_{\chi} \chi(a)^{-1} \sum_{p \leq x} \frac{\chi(p) \ln p}{p} = 2 \sum_{p \leq x} \frac{\ln p}{p} \]

on the other hand the left side is equal to,

using (a),

\[ \sum_{p \neq x} \frac{\ln p}{p} + \sum_{\chi \neq \chi_0} \chi(a)^{-1} \sum_{p \leq x} \frac{\chi(p) \ln p}{p} = \sum_{p \leq x} \frac{\ln p}{p} + o(1) ; \]

finally, putting these together with \( \pi_2 \) (ii-v)

we have

\[ \sum_{p \leq x} \frac{\ln p}{p} = \frac{1}{4} \sum_{p \leq x} \frac{\ln p}{p} + o(1) = \frac{1}{4} \ln x + o(1) ; \]

c) this follows immediately from (6) by taking \( a = 1, 2, 3, 4 \).
xxiv Numerical Characters
and the Dirichlet Theorem - Solutions

1. i) This is clear;

ii) by complete multiplicativity
\[ \chi(1) = \chi(1 \cdot 1) = \chi(1) \chi(1) ; \]
thus either \( \chi(1) = 0 \) or \( \chi(1) = 1 \); but \( \chi(1) = 0 \) is
prohibited from the definition since \( (1, k) = 1 \);

iii) by Euler's generalization of Fermat's
theorem (see IX \#7 (iii)) we know
\[ a^{\varphi(k)} \equiv 1 \pmod{k} ; \]
by periodicity and multiplicativity of \( \chi \) we
have \( (\chi(a))^{\varphi(k)} = \chi(a^{\varphi(k)}) = \chi(1) ; \) but by (ii)
\( \chi(1) = 1 \) so we are done;

w, v) by direct checking ;
vi) by (iii) for \((a, k) = 1\), \(\chi(a)\) is one of the \(\psi(k)\) roots of unity; since \((a, k) > 1\) implies \(\chi(a) = 0\) we clearly have no more than \(\psi(k)\) possible specifications for \(\chi\) on the set of a prime to \(k\);

vii) \((a, k) = 1\) implies \((a, d) = 1\) so \(\chi^*(a) = \chi(a) \neq 0\); if \((a, k) > 1\) then \(\chi^*(a) = 0\); if \((ab, k) = 1\) then \(\chi^*(ab) = 0 = \chi^*(a) \chi^*(b)\); if \((ab, k) = 1\) then \(\chi^*(ab) = \chi(a) \chi(b) = \chi^*(a) \chi^*(b)\);
finally if \(a \equiv b \pmod{k}\) then \((a, k) = (b, k)\) so if this is \(\geq 1\), \(\chi^*(a) = \chi^*(b) = 0\), while if this is equal to 1, \(\chi^*(a) = \chi(a)\), \(\chi^*(b) = \chi(b)\) and \(a \equiv b \pmod{d}\), so \(\chi^*(a) = \chi(a) = \chi(b) = \chi^*(b)\);

viii) since \(\chi\) is not principal there is an \(a\) with \(\chi(a) \neq 1\), \((a, k) = 1\); now \(a, 2a, \ldots, ka\) run over a complete system of residues modulo \(k\) so \(\chi(a) \sum_{n=1}^{k} \chi(n) = \sum_{n=1}^{k} \chi(an) = \sum_{n=1}^{k} \chi(n)\) and therefore,
\[(\chi(a) - 1) \sum_{n \equiv 1}^k \chi(n) = 0;\]
since \(\chi(a) - 1 \neq 0\) the conclusion follows;

ix) direct checking;

x) If not then there are two mod \(k\) characters, say \(\chi, \chi'\), such that \(\chi(a) \chi_1(a) = \chi'(a) \chi_1(a)\); but for \(\langle a, k \rangle = 1\) this means \(\chi(a) = \chi'(a)\); since \(\chi\) and \(\chi'\) are zero on all \(a\), \(\langle a, k \rangle > 1\), this implies \(\chi = \chi'\).

2. i-a) This is clear by direct checking;

b) for \(\chi(d) = 1\) with \((d, p^9) = 1\) we would have to have \(\lambda = 0\), which implies \(d \equiv 1 \pmod{p^9}\);

c) \((d, k) = 1\) and \(p^9 | k\) implies \((d, p^9) = 1\); thus by (b), \(\chi(d) \neq 1\); if we let \(\chi^*\) be the mod \(k\) extension of \(\chi\), see \(\equiv 1\) (vii), then

\(\chi^*(d) = \chi(d) \neq 1;\)
ii) since \( d \equiv -1 \pmod{4} \) we know \((d', k) = 1\) and \( \chi^*(d) = \chi(d') = -1 \);

(iii-a) first of all we note that, by the proof of xviii\( ^*\) 15 (iii), \( \chi \) is in fact defined for all odd \( n \); since the product of two odd numbers is of the form \( 4k+3 \) precisely when exactly one of them is of this form we see that \( \chi \), as defined, is completely multiplicative (this is clear when a factor is even); the rest is clear;

b) since \((d, k) = 1\) we know \((d', 2^\alpha) = 1\) and, therefore if \( \chi^* \) is the mod \( k \) extension of \( \chi \) we have \( \chi^*(d) = \chi(d') \); if \( \chi(d) = 1 \) then \( t=0 \) and \( d \equiv \pm 1 \pmod{2^\alpha} \), contrary to assumption; thus \( \chi^*(d') \neq 1 \);

iv) the hypotheses imply \( k \) is an integer greater than 2; thus either some odd prime divides \( k \), or \( k = 4 \), or \( k \) is divisible by 8;
in any event, by (i), (iii), (iii) there is a mod $\ell$ character such that $\chi(d) \neq 1$.

3. i) If $(a, k) \neq 1$ the result is clear; otherwise, if $a \equiv 1 \pmod{k}$ then the sum equals $\sum_{X} \chi(1) = c$, while, if $a \neq 1 \pmod{k}$ then, by $\#2(\omega)$, there is a $\chi_1$ with $\chi_1(a) \neq 1$; multiplying by $\chi_1(a)$ and recalling $\#1(x)$ we see

$$\chi_1(a) \sum_{X} \chi(a) = \sum_{X} (\chi_1 \chi)(a) = \sum_{X} \chi(a)$$

and, therefore, $(\chi_1(a) - 1) \sum_{X} \chi(a) = 0$; since $\chi_1(a) - 1 \neq 0$ the conclusion follows;

iii) using (i) at the 1$^\text{st}$ equality and $\#1(\text{viii})$ at the 3$^\text{rd}$ equality we have

$$c = \sum_{a=1}^{k} \sum_{X} \chi(a) = \sum_{X} \sum_{a=1}^{k} \chi(a) = \sum_{a=1}^{k} \chi_0(a) = \Phi(k);$$

iii) if $(n, k) \neq 1$ then the sum is zero; if $(n, k) = 1$ we may select $m$ so that $am \equiv n \pmod{k}$; note then, using (i) and (ii), that
\[ \sum_{x} \chi(a)^{-1} \chi(n) = \sum_{x} \chi(a)^{-1} \chi(a) \chi(m) = \sum_{x} \chi(m) \]

\[ = \begin{cases} \varphi(k) & \text{if } m \equiv 1 \pmod{k}; \\ 0 & \text{if } m \not\equiv 1 \pmod{k}; \end{cases} \]

but \( m \equiv 1 \pmod{k} \) is equivalent to \( a \equiv n \pmod{k} \) and we are done;

\( \text{i) since } \chi(a) \text{ is a root of unity, see } \#1(\text{ii}) , \\
\chi(a) \bar{\chi(a)} = 1; \text{ thus } \bar{\chi(a)} = \chi(a)^{-1} \text{ and the result is the same as } \#1(\text{ii}). \)

4. i) \( \frac{\chi(a)}{m} \) is an \( m^{th} \) root of unity and with the exception of 1 all of them satisfy the equation \( x \cdot \frac{x^{m-1}}{x-1} = x^m + \cdots + x = 0; \)

\( \text{ii) the 1st equality is immediate from } (i); \)

on the other hand
\[ \sum_{x} \sum_{j=1}^{m} \left( \frac{\chi(a)}{\omega} \right)^j = \sum_{j=1}^{m} \frac{1}{\omega^j} \sum_{x} \chi(a)^j = \sum_{j=1}^{m} \frac{1}{\omega^j} \sum_{x} \chi(a^j); \]

but, by \#3 (i), (ii), the inside sum on the right is 0 unless \( a^j \equiv 1 \pmod{k} \) when it is \( \varphi(k); \) since
only for \( j = m \) is the latter true we see that
the right hand expression is merely
\[
\frac{1}{\omega_m} \psi(k) = \psi(k).
\]

5. Taking \( f \) to be \( \chi \) and \( g(n) \), respectively,
to be \( \frac{1}{n} \), \( \frac{\log n}{n} \), \( \frac{1}{\sqrt{n}} \) in \( \text{xxiii} \ #1(iii) \) we obtain all
of these results.

6. i) Since \( \chi \) is multiplicative the multiplicativity
of \( F \) follows from \( \text{viii} \ #27(i) \); the expression
given for \( F(p_1^{\alpha_1} \ldots p_s^{\alpha_s}) \) is immediate from the
multiplicativity;

ii) this follows from the expression in (i)
and the observation
\[
\sum_{j=0}^{\alpha_i} \chi(p_i^j) = \chi(1) + \chi(p_i) + \chi(p_i^2) + \ldots + \chi(p_i^{\alpha_i}) =
\begin{cases} 
\alpha_i + 1 & \text{if } \chi(p_i) = 1 \\
1 & \text{if } \chi(p_i) = -1 \text{ and } \alpha_i \text{ is even or if } \chi(p_i) = 0 \\
0 & \text{if } \chi(p_i) = -1 \text{ and } \alpha_i \text{ is odd,}
\end{cases}
\]
plus the fact that for \( n^2 \) all \( \alpha_i \) are even;
iii) this is an immediate consequence of (ii) since \( \sum_{n=1}^{\infty} \frac{F(n)}{\sqrt{n}} \) has a subseries which dominates the harmonic series \( \sum_{n=1}^{\infty} \frac{1}{n} \);

iv) the 1st equality is clear from the definitions of \( G \) and \( F \); the 2nd follows from a consideration of the lattice points under the graph of \( dS=x \) in the graph to the right;

v) by comparing \( \sum_{d \leq \delta} \frac{1}{\sqrt{d}} \) and \( \sum_{d \leq \delta} \frac{1}{\sqrt{d}} \) with \( \int_{0}^{\delta} x^{-\frac{1}{2}} \, dx \) and \( \int_{0}^{\sqrt{x}} x^{-\frac{1}{2}} \, dx \) we have

\[
\sum_{d \leq \delta} \frac{1}{\sqrt{d}} = 2 \sqrt{\frac{x}{d}} + O(1) + O\left(\frac{\sqrt{\delta}}{\sqrt{x}}\right), \quad \sum_{d \leq \delta} \frac{1}{\sqrt{d}} = 2 \sqrt{\frac{x}{d}} + O(1) + O\left(\frac{1}{\sqrt{x}}\right);
\]

from the last part of (iv) we have

\[
\sum_{d \leq \delta} \frac{x(c_{d})}{\sqrt{d}} = O\left(\sqrt{\frac{x}{d}}\right) + O\left(\frac{1}{\sqrt{x}}\right);
\]

substituting these into (iv) and simplifying yields

\[
G(x) = 2 \sqrt{\frac{x}{d}} \sum_{d \leq \sqrt{x}} \frac{x(c_{d})}{d} + O(1) \sum_{d \leq \sqrt{x}} \frac{x(c_{d})}{\sqrt{d}} + O\left(\sqrt{\frac{x}{d}}\right) \sum_{d \leq \delta} \frac{1}{\sqrt{d}} + O\left(\frac{1}{\sqrt{x}}\right) \sum_{d \leq \delta} \frac{1}{\sqrt{d}}
\]

\[
= 2 \sqrt{\frac{x}{d}} \cdot L_{0}(x) + O(1) + O\left(\frac{1}{\sqrt{x}}\right) \left(2 \sqrt{\frac{x}{d}} + O(1) + O\left(\frac{1}{\sqrt{x}}\right)\right)
\]

\[
= 2 \sqrt{\frac{x}{d}} \cdot L_{0}(x) + O(1);
\]
vi) If \( L_0(x) = 0 \) then, from (v), \( G(x) = O(1) \) and this contradicts (iii).

7. i) Put \( P(n) = x(n), f(x) = x, g(x) = \sum_{n \leq x} \frac{x(n)}{n} \) into xxii 4 (ii), to obtain \( x = \sum_{m \leq x} N(m) x(m) g \left( \frac{x}{m} \right) \); now noting that, by #5, \( g(x) = x L_0(x) + O(1) \) and substituting we have

\[
x = \sum_{m \leq x} N(m) x(m) \left( \frac{x}{m} L_0(x) + O(1) \right)
\]

since the last sum is \( O(x) \) the desired result follows;

\[\text{(i-a)} \quad g(x) = x \ln x \sum_{n \leq x} \frac{x(n)}{n} - x \sum_{n \leq x} \frac{x(n) \ln n}{n}
\]

\[= x \ln x \left( L_0(x) + O(\frac{1}{x}) \right) - x \left( L_1(x) + O\left( \frac{\ln x}{x} \right) \right)
\]

\[= -x L_1(x) + O(\ln x) ;
\]

b) using xxii #4 (ii) on the expression for \( g(x) \), taking \( f(x) = x \ln x \), we find, using (a),

\[x \ln x = \sum_{n \leq x} N(n) x(n) g \left( \frac{x}{n} \right) = \sum_{n \leq x} N(n) x(n) \left( -\frac{x}{n} L_1(x) + O(\ln \frac{x}{n}) \right)
\]

\[= \sum_{n \leq x} \frac{N(n) x(n)}{n} + O \left( \sum_{n \leq x} \frac{\ln x}{n} \right) ;
\]

the desired conclusion now follows from xxiii #2 (iv) ;
iii) for \(L_0(X) = 0\) this follows from (ii) and for \(L_0(X) \neq 0\) this follows from (i).

8. This proceeds along lines similar to \(\pi_{22} \# 9(ii)\):

\[
\sum_{\mathfrak{p} \mid x} \frac{x(p) \ln p}{p} + O(1) = \sum_{\mathfrak{p} \mid x} \frac{x(p) \ln p}{p} + \sum_{j = 2}^{\infty} \sum_{\mathfrak{p} \mid x} \frac{x(p_j) \ln p_j}{p_j^j}
\]

\[
= \sum_{\mathfrak{n} \mid x} \frac{x(n) \lambda(n)}{n} = \sum_{d \mid x} \frac{\lambda(d) \chi(d)}{d} \sum_{\delta \mid d} \frac{x(\delta) \ln \delta}{\delta}
\]

\[
= \sum_{d \mid x} \frac{\lambda(d) \chi(d)}{d} \left(L_1(X) + O\left(\frac{\ln x/d}{x/d}\right)\right) = L_1(X) \sum_{d \mid x} \frac{\lambda(d) \chi(d)}{d} + O\left(\sum_{d \mid x} \ln \frac{x}{d}\right)
\]

\[
= L_1(X) \sum_{d \mid x} \frac{\lambda(d) \chi(d)}{d} + O(1);
\]

using \(\pi_{7}(iii)\) completes the proof.

9. i) By \(\pi_6(vi)\) no such \(X\) may be real; thus if \(L_0(X) \neq 0\) then \(L_0(\bar{X}) \neq 0\) and \(X \neq \bar{X}\); thus \(N\) is at least 2;

ii) the left inequality is clear; the 1st equality follows from \(\pi_3(i), (ii)\) since

\[
\sum_{X} \sum_{\mathfrak{p} \mid x} \frac{x(p) \ln p}{p} = \sum_{\mathfrak{p} \mid x} \frac{\ln p}{p} \sum_{X} X(p);
\]

finally, making use of \(\pi_8\) and \(\pi_{22} \# 2(v)\) we see
\[ \sum_{x \in S} \frac{x(p) \ln p}{p} = \sum_{p \neq x} \frac{x(p) \ln p}{p} + \sum_{L_\sigma(x) = 0} \frac{x(p) \ln p}{p} + \sum_{L_\sigma(x) \neq 0} \frac{x(p) \ln p}{p} = \ln x + O(1) + N(-\ln x + O(1)) + O(1) = (1 - N) \ln x + O(1); \]

iii-a) If \( N > 1 \) then the right side in (ii) would tend to \(-\infty\), contrary to the inequality there stated.

b) By #8 every contributor to the sum \( Q(x) \) is either \( O(1) \) or of the form \(-\ln x + O(1)\); this means that if some contributor were of the form \(-\ln x + O(1)\) then \( Q(x) \) would tend to \(-\infty\) as \( x \to \infty \); this contradicts (a); but then, by #8, every \( x \neq x_0 \) satisfies \( L_\sigma(x) \neq 0 \).

c) This follows from (b) and #8.

10. The 1st equality follows from #3 and the 2nd equality from #9(iii) and \( XXIII \#2(v) \); if there were only finitely many primes \( p \), \( p \equiv a \pmod k \) then the left side would be finite in contradiction to its being equal to \( \ln x + O(1) \).

Notation is integral to mathematical meaning, and where notation is displayed with more expressive flexibility than standard type allows, the clarity and continuity of the presentation is enhanced along with the appearance of the page. This proposition is demonstrated by this wholly hand-calligraphed book.

The approach of the text is almost as unusual as its format. Joe Roberts, Professor of Mathematics at Reed College, has devised a sequence of problems that will lead a student without much mathematical training or sophistication to an understanding of a number of the better known results of elementary number theory. The problems also offer a great many results that are simply interesting in themselves, and that are not usually included even in more advanced courses.

The chapters are largely independent, and can be undertaken by the serious student almost at random. However, it should be noted that some of the problems are really quite difficult, and no one should feel that consulting the second half of the book, in which solutions are presented in detail, is an admission of defeat - it is rather a means of access to a richer understanding.
